#### Abstract

#### **Introduction**

Despite comprising many cancer diagnoses, few treatments are suitable for patients with advanced non-small cell lung cancer (aNSCLC). Trials suggest blockade of Programmed Death 1 (PD1) or its ligand (PDL1) may be effective for these patients. However, this therapy's impact on outcomes other than survival, and outcomes of patients not in trials, remains largely unknown. Therefore, we compared the effectiveness of PD1 and PDL1 immunotherapy to chemotherapy and placebo across multiple clinical outcomes.

#### <u>Methods</u>

Six databases were searched on 12-13/10/2019 for randomised controlled trials (RCTs) and observational studies investigating nivolumab, pembrolizumab, atezolizumab or durvalumab. Study selection was performed independently by two reviewers. Data for overall survival, progression-free survival, adverse effects (AEs), and quality of life (QoL) were descriptively and meta-analysed. Factors impacting treatment outcomes, including PDL1 expression, were explored. The similarity between RCT and observational data was assessed.

#### Results

From 5,423 search results, 139 full texts and abstracts were included. Immunotherapy was associated with a lower risk of death than both comparators. In RCTs, the incidence of treatment-related AEs was approximately 20% lower among patients using immunotherapy compared to chemotherapy. However, no other consistent benefits were observed. Progression-free survival results were inconsistent. Improvements to QoL varied according to the instrument used; however, QoL was not recorded widely. Survival results were similar between study designs; however, AEs incidence was lower in observational studies.

#### **Discussion**

Among patients with aNSCLC, immunotherapy improved overall survival and incidence of treatment-related AEs compared to chemotherapy. Benefits to progression-free survival and QoL were less consistent.

(Word count: 249)

#### Key messages

#### What is already known on the topic?

In trials, PD1 and PDL1 immunotherapy improves overall survival, but the impact to other clinical outcomes, the extent to which trial data reflect clinical practice, and factors affecting outcomes from this therapy are less well understood.

#### What this study adds

We present comprehensive systematic review data from 26,581 patients, demonstrating that while this immunotherapy improves overall survival, benefits to progression-free survival and quality of life are less clear. Performance status and presence of metastases had potential influence on survival outcomes.

#### How this study might affect research, practice, or policy

This study may be used to provide information about multiple clinical outcomes to patients and contribute to understanding factors affecting patient outcomes, to identify those most likely to succeed with this therapy.

### Introduction

Globally and in the United Kingdom (UK), lung cancer is a major healthcare problem due to its high incidence and poor associated long-term survival [1-3]. In the UK, just 7.6% of men and 11.3% of women are predicted to survive past ten years [4]. Lung cancer incidence is strongly correlated with smoking, increasing age, and deprivation, suggesting vulnerable individuals are more susceptible [5-8].

Non-small cell lung cancer (NSCLC) is the most common type of lung cancer, comprising around 87% of cases [9]. The complex reasons for the poor prognosis associated with NSCLC have been widely studied [10]. One core reason is that many available treatments are unsuitable for patients with advanced NSCLC (aNSCLC), who comprise a large proportion of cases. Therefore, patient prognosis may be improved by identifying more treatments suitable for aNSCLC. Due to the specificity of antigen recognition within the immune system, therapies capitalising on immune checkpoint blockade, particularly Programmed Death 1 (PD1) and Programmed Death Ligand 1 (PDL1) immunotherapy, have potential to improve care of patients with aNSCLC.

PD1 and PDL1 immunotherapy consists of monoclonal antibodies that block the intra-tumoral interactions between PD1 and PDL1, restoring the cytotoxic functionality of anti-tumour immune cells [11, 12]. Based on data assimilated by the National Institute of Health and Care Excellence (NICE) from phase III randomized controlled trials (RCTs), PD1 and PDL1 immunotherapy has been recommended for the treatment of stage IIIB and stage IV NSCLC among patients expressing PDL1 [13].

However, several unanswered questions remain. Firstly, the generalisability of current NICE guidelines is questionable. This is because, by only considering trial data, the guidelines place emphasis on results from a few tightly regulated, relatively well, subsets of the population of NSCLC patients [14-18]. Secondly, available systematic reviews are limited because they focus on a single class effect, mostly related to short-term survival; assimilate data across several cancer types; and largely do not include observational data to assess real-world treatment-related outcomes [19-28]. Therefore, further systematic reviews are needed to provide a more realistic estimate of treatment effect and to investigate outcomes unrelated to survival. We aimed to establish whether PD1 and PDL1 immunotherapy is effective at improving clinical outcomes of NSCLC, compared to chemotherapy or placebo. Both RCTs and observational studies were included to assess data generalisable to a broad population. As a secondary objective, we explored potential patient and disease factors influencing patient prognosis.

#### Methods

The protocol is registered on PROSPERO (CRD42019153345).

#### Identification of relevant studies

All searches consisted of synonyms describing NSCLC, and PD1 and PDL1 immunotherapy, with database-specific subject headings where appropriate (see supplement). Studies in any language from inception to 13/10/2019 were included. Six databases were searched: Ovid Medline, Ovid EMBASE, EBSCO CINAHL, Cochrane Library, ClinicalTrials.gov and NICE Evidence Search. To check for relevant studies missed by literature searches, the reference lists of relevant systematic reviews returned from searches were compared against relevant results from title and abstract screening.

## Study screening, selection, and data extraction

Eligible studies were required to meet the criteria specified in the protocol (Table 1). Studies were excluded if there were insufficient data for analysis, or if these criteria were not met.

Population	Adults > 18 years old with squamous, large cell, or adenocarcinoma NSCLC in ≥90% of participants, or data presented separately for eligible patients.					
Intervention	monotherapy administ	Nivolumab, pembrolizumab, atezolizumab and durvalumab monotherapy administered by a healthcare professional in a secondary or tertiary healthcare setting.				
Comparator		mmended chemotherapy administered by als in a secondary or tertiary setting.				
Outcomes	Overall survival (OS) Time between initiation of treatment and dea of patient					
	Progression-free survival (PFS)Time between initiation of treatment and worsening of the patient's cancer or death					
	Adverse effects A healthcare problem that arises after initiating treatment					
	Quality of life (QoL)Patient's satisfaction with their standard of living while they are using a treatment					
	Hospitalisations					
Study designs	Randomised Controlled Trials (RCTs)	Those comparing the effectiveness of PD1 and PDL1 immunotherapy to either of the two comparators were eligible. Non-comparative trials were not eligible. Abstracts permitted.				
	Cohort and case control studies	Participant number ≥ 10, receiving PD1 or PDL1 immunotherapy. Abstracts permitted.				
	Case series and case	Case series and case reports were not eligible.				

### Table 1 – PICOS criteria

Search results were independently screened for relevance, and data were extracted by at least two reviewers at each stage. The data collected are outlined in the supplementary methods. When relevant data were unavailable, authors were contacted via e-mail.

### Risk of bias and quality assessment

Risk of bias was assessed at a study level by one author and checked by SSK using the revised tool for Risk of Bias in randomized trials (RoB2.0) for RCTs, and the 2016 Risk Of Bias In Non-randomized Studies of Interventions (ROBINS-I) as appropriate. The risk of publication bias was assessed using a funnel plot of the hazard ratios (HRs) for mortality from included RCTs, constructed in Review Manager 5.3<sup>™</sup>. Risk of bias data were visualised using the Risk Of Bias Visualisation Tool (ROBVIS). Additionally, the quality of RCT evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) framework; the GRADEpro<sup>™</sup> tool was used to produce a Summary of Findings table.

## Data analysis

All outcomes were analysed descriptively. Studies were grouped by follow up length for analysis (Table 2).

Reported length of follow up	Follow up classification in review
0 months $\leq x < 18$ months	Short-term follow up
18 months $\leq x < 31$ months	Medium-term follow up

$x \ge 31$ months	Long-term follow up

#### Table 2 – Classification of length of follow up

x = median follow up reported in study, or minimum follow up if median was unavailable. This classification was used because most primary-analysis studies reported a follow up of just over one year, which would not be a fair comparison against data collected from closer to 24 months follow-up.

Risk of death and risk of progression or death HRs from RCT studies were meta-analysed in Review Manager 5.3<sup>™</sup> using a random effects model. Meta-analysis was precluded in observational studies due to the lack of reported HRs in these largely single arm studies. Median survival times and 95% confidence intervals (CIs) are displayed in the supplement. To aid comparison between studies, we also show the simple arithmetic mean of median survival times ('average survival') in the supplement. These mean estimates are indicative only.

AEs data were directly reported as or were converted to percentage incidence, defined as the proportion of patients within the study arm who had each AE. These data were analysed descriptively and with simple means to provide summary estimates of incidence. Detailed AEs tables are presented in the supplement.

Quality of life (QoL) results were reported directly from included studies. Meta-analysis was precluded because multiple QoL questionnaires were used among the studies.

Subgroup meta-analyses of HRs stratified by PDL1 expression, therapy line, tumour histology, presence of metastases and performance status were performed via the same methods. Where a breakdown of results by therapy line was not reported, studies were grouped into a 'mixed' category for analysis. These analyses were only possible for survival data due to a lack of HRs and stratification of results, particularly in the observational data.

#### Results

#### Characteristics of studies

After removing duplicates, 5,423 records were screened by title and abstract. Subsequently, 277 full texts and abstracts were screened. From these, 101 full texts and 38 abstracts were included (Figure 1) [29].

The 28 RCT studies included primary, extended follow up, and comparative subgroup analyses of 12 phase II or III international trials comparing immunotherapy to docetaxel, combination platinum chemotherapy or a placebo. The 111 observational studies included 74 full texts and 37 abstracts. Most observational studies were non-comparative cohort studies of a single intervention used in real clinical practice, typically nivolumab.

Across all RCTs, the total number of patients was 7,727 (range 272-1,274/study). The total number of participants across all observational studies was 18,951 (10-1,588/study). Participants in RCTs and observational studies had similar baseline characteristics (Table 3), though reporting was inconsistent among abstracts. Patients were typically men aged between 58 – 75. In RCTs, most patients were Caucasian; few observational studies reported ethnicity. Participants were recruited internationally, although few patients were from Africa.

Most patients in RCTs had stage III, IV or recurrent NSCLC, and thus had metastatic disease. Similarly, despite recruiting patients with all stages of disease, most patients in observational studies had metastatic disease. Most trials restricted recruitment by NSCLC histology, unlike the observational studies. Across both study designs, most patients had non-squamous

disease. However, unlike the observational studies, all trial patients had an Eastern Co-Operative Oncology Group Performance Status (ECOG PS) between 0 – 1.

Median length of follow up was typically one year, with some extended follow up RCTs reporting outcomes from up to four years.

Several lines of therapy were investigated in both RCTs and observational studies. In some studies, multiple lines were investigated (see supplement).

Patient	Randomised Controlled Trials (RCTs)			Observational		
characteristic	Number of RCTs*	Mean (Range) for intervention	Mean (Range) for comparator	Number of studies*	Mean (Range)	
% male	11	67.1	64.6	86	68.5	
		(52.0 - 82.0)	(53.0 – 81.0)		(19.6 - 90.0)	
% Caucasian	6	79.1	81.8	9	65.1	
		(66.2 – 91.0)	(70.6 – 95.0)		(13.0 – 97.0)	
Median age	11	62.7	63.5	79	66.5	
(yrs)		(60.0 - 64.5)	(60.0 - 66.0)		(58.0 – 75.2)	
Non-squamous	11	65.2	67.8	87	64.6	
histology		(0.0 - 100.0)	(0.0 – 100.0)		(0.0 - 100.0)	

#### Table 3 – Baseline characteristics of patients

\*Not all studies reported all characteristics. Among the RCTs, Spigel et al did not report any baseline characteristics in their abstract [30]. Among the observational studies, absences of data largely originated from observational abstracts.

#### Risk of bias and quality of evidence

Overall, the risk of bias was relatively low (Figure 2A – C and supplement). Most RCTs and observational full texts were associated with a low risk of bias. The most common sources of bias in RCTs arose in domains relating to randomisation and intervention, attributable to the lack of reported compensatory mechanisms for potential crossover in open-label trials. The main source of bias in observational full texts arose from a lack of adjusting analyses for known confounders. Furthermore, approximately 40% of observational full texts did not report the implications of intervention deviations. The lack of reporting of methods in observational abstracts impacted our ability to assess risk of bias in these studies, which therefore remains unclear.

Funnel plots using HRs for death from RCTs were relatively symmetrical and are therefore unlikely to be subject to significant publication bias (Figure 2D). Our assessment gives no suggestion that conflicts of interest impacted the conduct of any of the studies included.

Using GRADE, the overall certainty of RCT evidence was moderate to high (Supplementary Results). Among studies investigating nivolumab, pembrolizumab and atezolizumab, time to deterioration in quality of life when assessed by EQ-5D-3L and LCSS ASBI were downgraded due to risk of bias, and risk of progression or death between 0 - 18 months were downgraded due to inconsistency and imprecision.

#### Overall survival

17 RCT studies reported OS at one- to four-years follow up [31-47]. 48 observational studies with short-term follow up reported OS [48-93]. Heterogeneity in the meta-analyses tended to be low to moderate, except for nivolumab in short-term follow up studies ( $I^2 = 71\%$ ).

Among RCTs with short-term follow up, patients receiving immunotherapy survived longer on average and had a lower risk of death than patients receiving chemotherapy. The pooled HR

Thorax

for death among patients receiving nivolumab, pembrolizumab or atezolizumab compared to chemotherapy was 0.75 (95% CI 0.69 – 0.81, p < 0.00001) (Figure 3A). Typically, average survival was approximately 3 months longer with immunotherapy, with pembrolizumab being associated with longest average OS (13.6 months; Supplementary Figure 1). However, the associated confidence intervals for these data overlap rendering this evidence unclear.

Among RCTs with medium-term follow up, patients receiving immunotherapy survived longer and had a lower risk of death. The pooled HR for death among patients receiving nivolumab, pembrolizumab or atezolizumab compared to chemotherapy was 0.72 (95% CI 0.65 - 0.80, p < 0.00001) (Figure 3B). Typically, average survival was around 5 months longer with immunotherapy compared to chemotherapy. OS was not reached among patients receiving durvalumab (Supplementary Figure 1); the risk of death was 0.68 (99.73% CI 0.47 - 1.00)[43].

RCTs with long-term follow up reported similar results. The pooled HR for death was 0.70 (95% CI 0.59 – 0.82, p < 0.0001) (Figure 4C). Only CheckMate017 and 057 reported OS between three- and four-year follow up. There was no change in median OS in either study arm of these two cohorts [46].

OS in observational studies and RCTs were similar (Supplementary Figure 1). The similarity in OS between observational studies and RCTs was supported by data from observational studies with an unknown length of follow up, and abstracts.

#### Progression-free survival

17 RCT studies reported PFS from up to three-years patient follow up [31-42, 44, 45, 94-96]. 52 observational studies with short-term follow up reported PFS [48-59, 63-72, 74-76, 78-85, 87-90, 92, 93, 97-104]. Heterogeneity in the meta-analysed studies tended to be high; the I<sup>2</sup> statistics for short-term follow up studies of nivolumab and pembrolizumab were 69% and 91% respectively.

In RCTs with short-term follow up, patients receiving immunotherapy had a lower risk of progression or death than patients receiving chemotherapy. The pooled HR for progression or death among patients receiving nivolumab, pembrolizumab or atezolizumab compared to chemotherapy was 0.87 (95% CI 0.76 – 0.99, p = 0.03) (Figure 5A). There was no evidence of a difference in average PFS among patients receiving nivolumab, pembrolizumab or atezolizumab and those receiving chemotherapy, albeit with some inconsistency within the results (Supplementary Figure 2) [94].

Among RCTs with medium or long-term follow up, patients receiving immunotherapy did not have a consistent benefit to PFS. At three-year follow up, the risk of progression or death among patients receiving nivolumab or pembrolizumab compared to chemotherapy was 0.82 (95% CI 0.74 – 0.90, p < 0.00001) (Figure 5B). However, there were no clinically significant differences in average PFS between these three agents and chemotherapy in medium or long term follow up studies (Supplementary Figure 2). In PACIFIC, the PFS was 17.3 months (95% CI 13.1 – 23.9) with durvalumab, compared to 5.6 months (95% CI 4.6 –7.7) on placebo [43].

Similar PFS results were reported in observational studies including those with an unknown length of follow up, and abstracts (Supplementary Figure 2).

#### Adverse effects and hospitalisations

20 RCT studies reported AEs [31-39, 42-44, 47, 94, 95, 105, 106]. 53 observational full texts reported AEs among patients receiving pembrolizumab, nivolumab and atezolizumab, of which 44 investigated nivolumab.

In primary-analysis RCT studies, nivolumab, pembrolizumab and atezolizumab were associated with a lower incidence of treatment-related adverse effects (trAEs) than chemotherapy (Table 4), except one atezolizumab study [69]. Durvalumab was associated with a similar incidence of trAEs [94].

	% incidence – mean (range)			
Drug	Intervention arm, Randomised Controlled Trials (RCTs)	Intervention, observational studies	Chemotherapy arm, RCTs <sup>†</sup>	
Nivolumab	65.2	50.6	87.3	
Nivolulliab	(58.0 – 71.0)	(21.0 - 88.0)	(83.0 – 92.0)	
Pembrolizumab	66.4	48.2	87.0	
	(63.0 – 73.4)	(10.0 – 71.0)	(81.0 – 90.0)	
Atozolizumoh	65.5		87.0	
Atezolizumab	(64.0 - 67.0)		(86.0 – 88.0)	
Overall	65.7	49.4	87.1	
	% incidence			
Drug	Intervention arm, RCT	Intervention, observational studies	Placebo arm, RCT	
Durvalumab*	67.8	•	53.4	

Table 4 – Incidence of trAEs among randomised controlled trials (RCTs) and observational studies

\*Only one study reported the incidence of trAEs among patients receiving durvalumab.

<sup>†</sup>Chemotherapy choices were highly variable between RCTs, but typically consisted of docetaxel or platinum-based chemotherapy combinations (see Supplementary Results).

The pattern and incidence of trAEs are summarised in Tables 5 and 6 and the supplementary results. Immune-related AEs were highly variable between studies and agents (see supplement).

Adverse effect	Number of	Mean % incidence		
	trials	Immunotherapy	Chemotherapy <sup>†</sup>	
Fatigue	9	15	27	
Decreased appetite	9	11	21	
Diarrhoea	8	11	15	
Pyrexia	3	11	7	
Nausea	8	10	31	
Rash	6	9	4	
Hypothyroidism	5	9	1	
Asthenia	7	8	12	
Arthralgia	3	7	8	
Constipation	5	6	12	

<u>Table 5 – Top 10 trAEs with the highest mean percentage incidence among patients receiving</u> <u>nivolumab, pembrolizumab, or atezolizumab in primary-analysis randomised controlled trials</u> (RCTs)

<sup>†</sup>Chemotherapy choices were highly variable between RCTs, but typically consisted of docetaxel or platinum-based chemotherapy combinations (see Supplementary Results).

Adverse effect	Number of studies	Mean % incidence
Fatigue/asthenia	24	27
Rash	25	13
Pruritus	12	11

Hypo-/hyperthyroidism	31	10
Nausea/vomiting	12	10
Arthralgia/myalgia	14	9
Diarrhoea	22	8
Neurological symptoms	10	8*
Pneumonitis	27	5
Anaemia	13	5

Table 6 – Top 10 trAEs with the highest mean percentage incidence among patients receiving nivolumab, pembrolizumab, or atezolizumab in observational studies

\*The mean percentage incidence for patients experiencing neurological symptoms was heavily positively skewed by one study, which reported a percentage incidence of 63%.

Manrique et al were the only study to report hospitalisations; in this study, 5 out of 188 patients receiving nivolumab (2.7%) were hospitalised due to AEs [107].

#### Quality of Life

Quality of life (QoL) was reported in 4 RCTs using either EQ-5D (3L or 5L), EORTC-QLQ (LC13 or C30) or LCSS (Table 7).

Reck et al reported no significant differences to benefit in EQ-5D-3L between nivolumab and docetaxel [108]. While patients in both KEYNOTE 024 trial arms improved in EQ-5D-3L, the difference between pembrolizumab and chemotherapy was not significant [109]. Hui et al reported a mean change in EQ-5D-5L of -0.014 ( $\sigma$  0.177) with durvalumab and 0.012 ( $\sigma$  0.122) on placebo [110].

The proportion of patients that improved in terms of Lung Cancer Symptom Scale (LCSS) by week 12 was 17.8% with nivolumab (95% CI 13.6% – 22.7%) and 19.7% with docetaxel (95% CI 15.2% – 24.7%) [108]. The time to deterioration in average symptom burden index (ASBI) in the LCSS was prolonged with nivolumab, despite an initial worsening at week 4 [108].

EORTC-QLQ-C30 was used in studies of pembrolizumab, atezolizumab and durvalumab Patients taking pembrolizumab experienced a mean improvement of 6.9 points (95% CI 3.3 – 10.6) between baseline and week 15 [109]. By contrast, patients in the chemotherapy arm experienced mean decline of 0.9 points (95% CI -4.8 – 3.0; p = 0.002) [109]. However, there was no significant difference between atezolizumab and docetaxel or durvalumab and placebo (Table 5) [110, 111].

Beneficial effects on EORTC-QLQ-LC13 score were observed with pembrolizumab and atezolizumab compared to chemotherapy and docetaxel, respectively [109, 111]. There were no clinically important EORTC-QLQ-LC13 between-group differences between patients using durvalumab and placebo [110].

Study	Drug	QoL Tool	QoL Measure	HR	95% CI	p value
Reck et al, 2018 [108]	Nivolumab	EQ-5D-3L [112]	Time to disease- related deterioration	0.90	0.69 – 1.17	0.424
		LCSS ASBI [113]	Time to disease- related deterioration	0.65	0.49 – 0.85	0.002

<u>Table 7 – Time to deterioration in quality of life, comparing interventions to chemotherapy and placebo</u>

The time to deterioration was prolonged among patients using an intervention [108-111]. The HRs have been reported directly from the included studies listed in the table.

#### Patient and disease factors influencing prognosis

Among 9 meta-analysable RCTs, increasing PDL1 expression was associated with a reduced risk of death (Figure 5). However, the CIs overlapped between groups, and there was significant heterogeneity among data from patients with  $\geq$ 5% expression. A similar relationship was observed between PDL1 expression and risk of progression or death (Supplementary Figure 5). When considering the current PDL1 expression threshold for accessing immunotherapy, patients with  $\geq$ 1% expression has a 6% lower risk of death than patients with <1% expression in these RCTs (Figure 5). However, the CIs between the two groups overlapped. Additionally, in 4 observational studies comparing this threshold among patients with nivolumab, no difference between risk of death for patients with <1% compared to  $\geq$ 1% was observed (Supplementary Figure 6). This result is hindered by the fact that one of these studies recruited patients involved in a compassionate access programme [116].

Among 10 RCTs with analysable therapy line data, patients receiving immunotherapy as 2<sup>nd</sup> line therapy had a 13% lower risk of death and a 12% lower risk of progression or death (Supplementary Figure 7). However, heterogeneity was significant in these subgroups.

No consistent impact to risk of death, or risk of progression or death, was observed when comparing patients with squamous to patients with non-squamous disease in 9 RCTs. This finding was upheld among the 10 observational studies comparing these subgroups.

2 RCT studies reported that patients with CNS and liver metastases receiving immunotherapy had a similar risk of death to patients without [44, 117]. However, the meta-analysed risk of death from 5 observational studies was significantly higher among patients with metastases (HR 1.69, 95% CI 1.23 – 2.32).

Among the 14 observational studies reporting the impact of ECOG PS on risk of death, patients with PS2 were at greater risk of death than patients with PS 0 – 1. The meta-analysed risk of death in 3 observational studies comparing PS2 to PS 0 – 1 was 1.95 (95% CI 1.54 – 2.48).

#### Discussion

Our results suggest PD1 and PDL1 immunotherapy increases OS and reduces risk of death from aNSCLC, based on numerous RCTs and observational studies with a relatively low risk of bias. This result replicates and builds upon previous reviews by demonstrating the impact of this therapy on OS is consistent both across study designs and at extended periods of follow up.

We extended previous systematic reviews by looking at other outcomes in detail; however, benefits to PFS, AEs and QoL were less clear. While risk of progression or death was reduced by immunotherapy, benefits to average PFS were variable. Additionally, although a benefit to trAE incidence was observed among patients receiving immunotherapy, the overall profile of AEs was similar between immunotherapy and chemotherapy. Furthermore, immune-related AEs were more common among patients using PD1-targeting treatments. Compared to RCTs, the incidence of AEs among patients using immunotherapy in observational studies was lower, although a broader range of AEs was reported in these studies. The impact of PD1 and PDL1 immunotherapy on patient QoL was variable, and highly dependent on the choice of instrument used in each study. There was a notable lack of QoL data, particularly among observational studies.

These results highlight the importance of distinguishing between the biological impact of PD1 and PDL1 immunotherapy and the impact of study design on results. Differentiating these may improve study designs to capture these effects.

The absence of a clear association between OS and PFS could be explained by pseudoprogression, which is a phenomenon in which immune cells infiltrate the primary tumour causing an increase to tumour size that mimics tumour growth [118]. Although there is limited evidence to support this theory, Li et al. found that mice with induced lung tumours exposed to anti-PD1 therapy accumulated tumour-infiltrating-lymphocytes within their tumours [119]. Since the included studies measured progression via the RECIST 1.1 criteria, which relies upon changes in tumour diameter, they were potentially unable to distinguish pseudoprogressions from true disease progression [120]. However, this explanation less probable, given the consistent effect of immunotherapy on the risk of progression or death. More likely, the lack of association may be explained by aspects of study design. Particularly, some of the included trials may be affected by bias introduced by calculating PFS from censored data [121]. Furthermore, many studies recruited patients from multiple therapy lines. Patients receiving later lines are more likely to have a shorter PFS, which may have meant studies investigating these reported lower median survival results.

The variability of AEs between drugs and study designs may also be explained by the effect of study design. Given all four therapies have a similar molecular basis, it is unlikely the differences in AE incidence between drugs are attributable to pharmacological effects. However, the lack of restriction of patients based on ECOG PS in observational studies may have contributed to the broader range of AEs observed, as patients with a higher ECOG PS could have a greater propensity to develop AEs. Furthermore, the retrospective nature of many observational studies may have allowed greater flexibility in detecting AEs compared to RCTs.

The choice of QoL tool impacted QoL results. While EQ-5D, a non-specific tool, was associated with minimal changes to QoL, patients assessed via more lung cancer-specific tools such as LCSS experienced greater benefits, suggesting this therapy may yet impact QoL when the correct tool is used. There is currently little research investigating impact of choice of QoL instrument on results [122]. Some studies have argued that lower AE incidence is indicative of improved QoL. However, given that QoL is a proxy measure of patient experiences with their wellbeing and care, assessments of QoL should reflect this and not rely solely upon the absence of disease.

We also extend current knowledge of factors influencing patient prognosis. Increasing PDL1 expression was associated with a lower risk of death, and risk of progression or death. However, the significance of the current PDL1 threshold for accessing this therapy, ≥1% expression, was unclear. Presence of metastases and ECOG PS2 were associated with worse

survival outcomes, while the impact of therapy line was not clear. It is unsurprising that presence of metastases and ECOG PS, which reflect patient health, were associated with poorer survival outcomes. However, it was more unexpected that having ≥1% expression did not confer a significant survival benefit. A potential reason for this may be that PDL1 expression is known to vary within tumours, and so samples of the tumour may not reflect overall tumour PDL1 expression. Therefore, there may have been insufficient PDL1 expression overall to experience a benefit among some patients, despite having ≥1% expression in their samples. This suggests more research is required to find the optimum threshold by which to stratify patients, or better ways to quantify PDL1 expression.

There are several limitations to the study. Firstly, some relevant abstract and ClinicalTrials.gov protocols could not be included due to the lack of methods and outcome data needed for analysis. Secondly, risk of publication bias among observational studies could not be assessed because too few studies reported HRs to be able to construct a funnel plot. The potential for publication bias limits the extent to which we can be confident results from observational studies represent patients in real clinical practice, as it is unknown whether outcomes of patients who do not benefit are underreported in available literature. Thirdly, the lack of comparative RCTs meant it was not possible to directly compare and confirm survival benefits observed between immunotherapies. Fourthly, it was not possible to meta-analyse the results from single arm observational studies, which prevented us from generating a summary estimate of treatment effectiveness from these studies. Finally, the study is hindered by the heterogeneity of the patient population. While we have explored some factors likely to affect patient outcomes, the variability in reporting the lines of therapy used in each study precluded our ability to fully explore the impact of this important factor. While our study had potential to be limited by comparing this therapy to chemotherapy solely recognised by NICE, we believe this is unlikely because NICE recommends a range of chemotherapy options in line with internationally accepted guidelines and evidence [13, 123, 124].

To conclude, among patients with aNSCLC, immunotherapy improved overall survival and incidence of treatment-related AEs compared to chemotherapy. Benefits to progression-free survival and QoL were less consistent. The variable effectiveness of this therapy to some outcomes and the expenses associated with its use suggest determining patients most likely to benefit is a key topic for future research or evidence syntheses.

#### **Contributor Statement**

SSK was the lead author of the study. Roles included: planning study methods; writing the PROSPERO protocol; literature searches; screening study titles and abstracts; checking inclusions and exclusions, and bias assessments of relevant studies; data analysis and writing and editing the submitted manuscript.

The roles of AT were: screening study titles and abstracts, screening relevant studies, extracting data from included studies and completing the primary risk of bias assessments.

The roles of VS and PB were: screening relevant studies, extracting data from included studies and completing the primary risk of bias assessments.

The roles of MJP were: assisting in the editing of figures, assisting in the meta-analysis of data, and editing the submitted manuscript.

AMT was the supervisor of the study. Roles included: planning study methods, editing the PROSPERO protocol, screening study titles and abstracts, and writing and editing the submitted manuscript.

All authors commented on drafts of the article and have approved the final version.

#### **Funding Declaration**

SSK received financial support as of February 2020 from the Yorke Williams Bequest, to support the completion of an associated thesis as part of an intercalated BMedSc in Clinical Sciences.

None of the remaining authors received funding related to this project. AMT has current grant funding from the NIHR, Health Foundation, ATS Foundation, Alpha 1 Foundation, CSL Behring, Chiesi and AstraZeneca (unrelated to lung cancer). MJP is supported by the NIHR Birmingham Biomedical Research Centre.

#### **Competing Interests**

None to declare. The views expressed are those of the authors and not necessarily those of the NHS, NIHR or the Department of Health and Social Care.

#### **Ethics Statement**

Ethical approval was not required for this study, because all data sourced and analysed were previously published anonymised patient data. No human participants were directly involved.

<u>Figure 2 – Risk of Bias Assessment Summary</u> A) Risk of bias summary bar chart for all included RCTs full texts and abstracts, assessed by ROB 2.0, B) Risk of bias summary bar chart for all included observational full texts, assessed by ROBINS-I, C) Risk of bias summary bar chart for all included observational abstracts, assessed by ROBINS-I, D) Funnel plot for publication bias, derived from HRs for overall survival at one year follow up from 10 RCTs. A 95% confidence region could not be plotted. This is because calculating a total risk from this data was not appropriate, as the included RCTs tested different interventions.

#### Risk of bias assessment

	D1	D2	D3	us domains D4	D5	Overall	Reasons for overall bias assessment from two reviewers
Brahmer 2015	+	-	+	+	+	+	Open-label, so potential for crossover is high. However, intention-to-treat analysis was used More patients using intervention discontinued; impact of patient characteristics not discusse
Carbone 2017	X	+	+	-	-	-	Open-label trial, so potential for crossover is high. However, the primary end point of PFS was assessed by blinded central review; details of this are not specified.
Borghaei 2015	X	-	+	+	+	-	Open-label trial, so potential for crossover is high
Wu 2019	•	+	+	+	+	+	Randomisation process specified, but no intention-to-treat analysis mentioned.
Reck 2018	X	X	+	-	+	X	Open-label trial, so potential for crossover is high. No details provided about the causes of losses to follow up, and the proportion in each treatment arm.
Heilmann 2018	•	+	+	+	+	-	Randomisation process specified, but no intention-to-treat analysis mentioned.
Heilmann 2019	-	+	+	+	+	-	Randomisation process specified, but no intention-to-treat analysis mentioned.
Antonia 2019	X	X	+	+	+	-	Analysis of two open-label trials, so potential for crossover is high. Adverse effects and deaths were causes of treatment cessation, but were not compared between trial arms.
Horn 2017	+	+	+	+	+	+	Randomisation process outlined clearly. Equal distribution of withdrawals and causes of withdrawals between trial arms. Intention-to-treat analysis was used.
Vokes 2019	•	X	+	X	+		The distribution of reasons for stopping treatment were not described. No intention-to-treat analysis used
Herbst 2016	+	+	+	-	+	+	Adverse effects were solely patient reported; potential for subjectivity depending on patient coping mechanisms and intuition to report.
Herbst 2019	+	+	+	+	+	+	Open-label trial, so potential for crossover is high. However, intention-to-treat analysis was used.
Brahmer 2017	+	+	+	+	+	+	Clear description of unbiased randomisation process. Consistent reporting of compliance to quality of life questionnaires. Several quality of life tools used.
Reck 2016	+	+	+	+	+	+	Open-label trial, so potential for crossover is high. However, intention-to-treat analysis is used. Blinded independent central radiological review used.
Reck 2019	+	+	+	+	+	+	Open-label trial, so potential for crossover is high. However, intention-to-treat analysis is used.
Mok 2019	+	-	+	+	+	+	Clear description of unbiased randomisation process. Adverse effects were described as leading to discontinuation; however, impact of patient characteristics not discussed.
Nosaki 2019	+	-	+	-	-	-	Open-label trial; however, intention-to-treat analysis was used. Higher rate of discontinuatio due to AEs in chemotherapy group; impact of patient characteristics not discussed.
Bordoni 2018	+	+	+	+	-	+	Several types of analyses conducted without explanation of reasoning behind analysis plan or the results presented
Fehrenbacher 2018	+	-	+	-	-	-	No information about intervention deviations due to experimental context. Pooled analysis of two populations, as protocol was amended. May be differences between populations.
Gadgeel 2019	+	+	+	+	-	+	Reason for point of step down of follow up not justified in the context of natural history of progression of disease.
Hida 2018	+	+	-	+	+	+	No information about losses to follow up. However, intention-to-treat analysis was used.
Rittmeyer 2017	X	+	+	+	+	-	Open-label and allocation unmasked, so very possible for crossover to occur. However, intention-to-treat-analysis was used.
Von Pawel 2019	+	-	+	+	+	+	No details of the extent of masking or blinding, so the impact of crossover is unknown. However, intention-to-treat analysis was used. Clear definition used for subgroup analysis.
Antonia 2017	+	+	+	+	+	+	Patients blinded to intervention or placebo. Clear specification of randomisation process. Intention-to-treat analysis used.
Antonia 2018	+	+	+	+	+	+	Patients blinded to intervention or placebo. Clear specification of randomisation process. Intention-to-treat analysis used.
Hui 2019	+	+	+	+	+	+	Clear description of unbiased randomisation process. Patients blinded to intervention or placebo. Intention-to-treat analysis used.
Fehrenbacher 2016	+	-	+	-	+	-	Open-label; however, intention-to-treat analysis was used. Withdrawals mentioned, but impact of patient characteristics not discussed. Concern regarding focus on intervention
Spigel 2019	-	X	+	+	-	-	Very little information provided regarding randomisation, receipt of intended intervention, an justification of outcomes, due to abstract format.

Thorax

#### ROB 2.0 assessment

The figure shows a traffic light assessment, generated using ROBVIS, and accompanying reasoning for the overall risk from the assessing authors.

	D1 D2	Risk of blas dor D3 D4 D5		Overall	Reasons for overall bias assessment from two reviewers
Alama 2019	<b>-</b>	++-	-	-	Lack of information on how participants were selected for the study, whether participants were excluded due to missing data, and how study outcomes were ascertained.
Bagley 2017	++	++-	•	+	Lack of information regarding whether participants were excluded due to missing information and how survival outcomes were ascertained
Bins 2018	++	••-	-+	-	Lack of information regarding whether participants were excluded due to missing information and how survival outcomes were ascertained. Reasoning behind 7 investigated single nucleotide polymorphisms is not explicit.
Brustugun 2016	-+	++-	-+	-	Authors did not account for the impact of smoking on patient outcomes. No information on exclusions due to missin information. Time to treatment failure was not defined, which could introduce systematic errors in assessment.
Crino 2019a	-+	+++	-	•	No methods for accounting for confounding factors mentioned. Lack of information regarding whether participants were excluded due to missing information and how survival outcomes were ascertained.
Crino 2019b	-+	+++	++	+	No methods for accounting for confounding factors mentioned.
Diem 2017	+-	<b>+ + -</b>	++	•	Given the aim of the study was to investigate blood parameters as markers of effectiveness, there is potential for exclusion of patients with incomplete blood results. No discussion of this in the study.
Dudnik 2018	++	•••	-+	•	Exclusions based on inadequate follow up may introduce a bias against patients who did not meet minimum follow requirement due to medical reasons relating to therapy. No clarification of this within the study.
Dumenil 2018	++	+++	-+	+	The information used in the study was highly dependent on availability in medical charts which, in turn, is dependen on completeness of clinical assessment and recording. No discussion of how this was addressed.
Dusselier 2019	+-	<b>+</b> - <b>+</b>	-+	-	Given the aim of the study was to investigate blood parameters as markers of effectiveness, there is potential for exclusion of patients with incomplete blood results. No discussion of this in the study.
Edahiro 2019	<b>+</b> -	+++	-	-	Lack of information regarding whether participants were excluded due to missing information and how survival outcomes were ascertained
Fujita 2019	++	+?+	++	+	No information regarding intervention deviations.
Fukihara 2019	++	<b>+</b>	++	+	The study subdivided patients into groups of patients who experienced or did not experience immune related pneumonitis; likely to be differences in patient characteristics that also affect susceptibility, which were not discuss
Fukui 2018	++	<b>+</b>	••	-	No information provided about missing data among patients or deviations, and any potential exclusions resulting fr this.
Garassino 2018	++	+ 🛛 -	++	-	A very high rate of discontinuation was observed in this study, which largely originated from patients who had neve smoked. The authors potentially attribute this to differences in turnour mutational burden.
Garde-Noguera 2018	++	<b>+</b>	++	+	Lack of information regarding whether participants deviated from their intended interventions and how survival outcomes were ascertained.
Garon 2015	-+	<b>+</b>	-+	-	Only PDL1 expression was accounted for in the main text. No information on deviations from intervention beyond expectation.
Garon 2019	-+	++-	••	-	While more potential confounders are accounted for in this text, it is unclear how complete the control of these confounders is. No information on deviations from intervention beyond expectation, or patients exclusions.
Gauvain 2018	++	<b>+</b>	++	+	Lack of information regarding whether participants deviated from their intended interventions and how survival outcomes were ascertained.
Geier 2018	+-	++-	•••	-	Little information regarding outcomes of all participants and exclusions. Unclear whether predictive factors of efficat were calculated using data from responders alone, rather than contrasting to non-responders.
Genova 2019	++	+++	•	+	Many different outcome measures are investigated, and two distinct cohorts of patients were used to compare and contrast the impact of B7-H4 as a biomarker of effectiveness.
Grossi 2018	++	+++		+	No notable problems
Haratani 2017	+-	<b>+ + -</b>	•	-	Selection of EGFR mutation positive patients on record only. The proportion of participants who had to be censore not stated.
Haratani 2018	-+	+?-	•	•	No information regarding deviations from interventions
Hasan Ali 2016	++	+?+	•	+	No information regarding deviations from interventions
Incue 2018	++	<b>+</b>	••	+	Little information regarding the proportion of participants who deviated from the intervention or for whom there was missing data.
Kaderbhai 2017	++	+++	++	+	No notable problems.
Kanai 2018	++	+++	++	+	No notable problems.
Karantanos 2018	++	+?+	++	+	No notable problems, although there was no information regarding patient deviations from interventions.
Katsura 2019	-+	<b>+</b> - <b>+</b>	•••	•	Potential for confounding from factors potentially influencing patient outcomes; little information regarding deviation from intervention
Kawachi 2019	-+	+++	++	+	In spite of recording baseline characteristics of potential confounders, there is potential for confounding from facto potentially influencing patient outcomes, such as smoking history and ECOG PS.
Kobayashi 2017	+ -	+?+	++	+	No information regarding deviations from interventions
Kobayashi 2018	++	+++	• •	+	Several measures of survival-related outcome effectiveness measures were used, which increases the scope to detect an effect but no speculation on impact of outcome choice on results
Krefting 2019	-+	+++	++	+	In spite of recording baseline characteristics of potential confounders, there is potential for confounding from facto potentially influencing patient outcomes, such as smoking history and ECOG PS.
Ksienski 2019a	++	<b>+</b> - <b>+</b>	••	+	Little information regarding deviations from interventions
Ksienski 2019b	++	+++	++	+	No notable problems.

### **GRADE Working Group grades of evidence**

**High certainty:** we are very confident that the true effect lies close to that of the estimate of the effect.

**Moderate certainty:** we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

**Low certainty:** our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

Supplementary Figure 4 – Incidence of AEs in observational studies

Table illustrating the percentage incidence of AEs in observational studies. Each block corresponds to the proportion of patients with each AE in the study, expressed as a percentage. [48-51, 53, 56, 57, 62-66, 68-76, 78, 79, 81, 83-85, 88, 89, 92, 94, 96-98, 101, 107, 125, 128, 132, 133].

#### Immune-related adverse effects

Immune-related adverse effects (irAEs) were more common among patients using an intervention compared to chemotherapy and less frequent than trAEs. The mean incidence of irAEs among patients receiving pembrolizumab in RCTs was 24.1% (range 19.0% – 29.2%). Similarly, the mean incidence of irAEs was 27.9% (range 17.0% – 43.0%) among the 7 observational studies investigating pembrolizumab. By contrast, the mean incidence of irAEs across the chemotherapy arms of RCTs investigating pembrolizumab was 5.3%, (range 4.2% – 7.0%). Unlike the RCTs, 10 observational studies reported the incidence of irAEs among patients using nivolumab; the mean incidence of irAEs was 37.5% (range 18.1% – 62.8%).

, a mi yroidism. a pembroli. (6.6%) and pne. highest mean in yneumonitis (5.9%). With a mean incidence of 9.3%, the most common irAE among patients receiving pembrolizumab in RCTs was hypothyroidism. Similarly, the irAEs with the highest mean incidence among patients using pembrolizumab in observational studies were hypothyroidism (7.2%), dermatitis (6.6%) and pneumonitis (4.6%). Among patients receiving nivolumab, the irAEs with the highest mean incidence were hypothyroidism (11.1%), hyperthyroidism (10.8%) and pneumonitis (5.9%).
