ABSTRACT

Background

Primary Sjögren syndrome (pSjS) is a chronic autoimmune disorder characterized by mucosal dryness and systemic symptoms. We tested the effects of inhibition of cathepsin S using the potent and selective inhibitor RO5459072 on disease activity and symptoms of pSjS.

Methods

This was a randomized, double-blind, placebo-controlled, parallel-group, Phase IIA study to investigate the effects of RO5459072 (100 mg twice daily [BID]; 200 mg per day). Seventy-five patients with pSjS were randomized 1:1 to receive either RO5459072 or placebo for 12 weeks. The primary outcome was the proportion of patients with a ≥ 3 point reduction from baseline in European League against Rheumatism (EULAR) Sjögren's Syndrome Disease Activity Index (ESSDAI) score. We also investigated the effects of RO5459072 on quality of life, exocrine gland function, biomarkers related to Sjögren's syndrome, and safety and tolerability.

Results

The proportion of patients showing an improvement in ESSDAI score was not significantly different between the RO5459072 and placebo arms. No clinically meaningful treatment effects were observed in favor of RO5459072 for all secondary outcomes. Analysis of soluble biomarkers indicated target engagement between RO5459072 and cathepsin S. There were modest decreases in the number of circulating B-cells and T-cells in the RO5459072 group, although these did not reach significance. RO5459072 was safe and well-tolerated.

Conclusions

There was no clinically relevant improvement in ESSDAI score (primary endpoint), and no apparent benefit in favor of RO5459072 in any of the secondary endpoints. Further work is needed in order to understand the mechanisms of MHC-II-mediated immune stimulation in pSjS.

Trial registration: ClinicalTrials.gov NCT02701985

Key words: Primary Sjögren syndrome, cathepsin S, ESSDAI, phase II, placebo

Rheumatology Key Messages

- The cathepsin S inhibitor RO5459072 did not confer a clinically meaningful benefit in patients with primary Sjögren syndrome.
- Cathepsin S may not be a relevant therapeutic target for treatment of primary Sjogren syndrome.

INTRODUCTION

Primary Sjögren's syndrome (pSjS) is a chronic autoimmune disease which is characterized by sicca and mainly involves the exocrine glands, affecting between 0.1-0.4% of the population depending on the country [1-3]. Lymphocytic infiltration of the exocrine glands and epithelia is the underlying driver of disease pathology, ultimately resulting in secretory gland dysfunction and dryness of the mucosal surfaces, such as the eyes and mouth [4]. Patients also exhibit a wide array of systemic symptoms, such as fatigue, neuropathy, muscle and joint pain, and some experience life-threatening immunological manifestations such as encephalitis, vasculitis, and lymphoma [5].

The pathogenesis of pSjS is not fully understood, but multiple factors appear to be involved. Among the key steps are the entry of follicular B-cells and T-cells into exocrine glands, increased cytokine production, B-cell hyperactivity, and autoantibody production [6, 7]. Other immune cells and chemokines have also been shown to participate in the destruction of glandular architecture, underscoring the complexity of this systemic disorder. To date, there is no disease-modifying therapy. Treatment revolves around supportive therapy (i.e. exercise for treatment of fatigue [8]), symptomatic management [9], and various systemic therapies [10]).

Cathepsin S is a cysteine protease that is expressed in antigen-presenting cells (APCs) including macrophages, B-cells and dendritic cells [11]. One of its main roles is the cleavage of the MHC-II-bound invariant chain pro-peptide Lip10 (p10), during the processing of MHC-II antigen-peptide complexes [12, 13]. There is evidence that elevated cathepsin S activity may lead to increased MHC-II expression and autoimmunity, implying that inhibition of cathepsin S may be a potential approach in attenuating auto-antigenic T-cell responses [14]. In keeping with this, the tears of patients with primary and secondary Sjögren's syndrome contain higher levels of cathepsin S activity compared to healthy individuals or those with other autoimmune diseases [15, 16]. Inhibition of cathepsin S in murine models of Sjögren's syndrome reduced inflammation of the lacrimal and salivary glands and improved the secretion of tears and saliva [14, 17].

RO5459072 is a covalent, reversible and selective inhibitor of cathepsin S developed for the treatment of autoimmune conditions, including Sjögren's syndrome [18]. Inhibition of cathepsin S by RO5459072 is expected to reduce MHC-II - mediated antigen presentation, and attenuate the activation of CD4⁺ T-cells. This would result in suppression of T-cell dependent autoantibody production and neutralization of the tissue damage caused by activated

macrophages and neutrophils [19]. Results from pre-clinical studies suggest that inhibition of cathepsin S by RO5459072 could result in decreased MHC-II maturation and reduced antigen presentation, representing a novel treatment strategy for pSjS [12, 19, 20].

The objective of this study was to investigate the effects of RO5459072 on disease activity and symptoms in patients with pSjS. The safety and tolerability of RO5459072 was also assessed in our study population of patients with moderate to severe pSjS.

METHODS

The protocol for this study and CONSORT checklist are available as Supplementary Information.

Study design

This was a randomized, double-blind, placebo-controlled, parallel-group Phase IIA trial designed to evaluate the effects of RO5459072 treatment on disease activity and symptoms in adult patients with moderate to severe pSjS. Patients were randomized 1:1 to receive either oral RO5459072 (100 mg twice daily [BID], total of 200 mg daily) or matching placebo, and were treated for a maximum of 12 weeks. Patients were recruited between July 2016-March 2017 in the US (9 centers), France (3 centers), UK (4 centers), Germany (1 center), Poland (3 centers), and Portugal (3 centers).

Study participants

We enrolled male and female adults (18-75 years) with moderate to severe pSjS, previously diagnosed according to the revised American-European Consensus Group criteria. The study flow diagram is given in Figure 1.

The severity of disease activity was defined according to the European League against Rheumatism (EULAR) Sjögren's Syndrome Disease Activity Index (ESSDAI) score of ≥ 5 . Patients also had to have a Sjögren's Syndrome Patient Reported Index (ESSPRI) score of ≥ 5 , and elevated serum titers of anti-SSA and/or anti-SSB antibodies at screening. We excluded patients with secondary Sjögren's syndrome, and those with severe complications of Sjögren's syndrome (including vasculitis with renal, neurologic or cardiac involvement; interstitial lung disease and severe myositis). Prohibited concomitant medications included: corticosteroid therapy exceeding the equivalent of 7.5 mg prednisone per day, anti-CD20 therapy (e.g. rituximab) or other B-cell-depleting therapy within 6 months of screening, immunosuppressant therapy, and cyclophosphamide.

Study treatment and randomization

RO5459072 (two hard gelatin capsules containing 50 mg drug substance) or matching placebo was taken orally twice daily with food (morning and evening) for 12 weeks. The investigators, patients, and study site staff were blinded to the treatment allocation.

Study assessments and endpoints

Assessments of Sjögren's syndrome disease activity, symptoms, and quality of life were carried out before (at baseline), during, and upon completion of the study treatment phase, at early termination visits, and at the safety and follow-up visit (Figure 2). Patients also underwent assessments of exocrine gland function and provided samples for measurement of biomarkers related to pSjS or the mechanism of action of RO5459072. Safety and tolerability were assessed throughout the study. Consenting patients also underwent minor salivary gland (MSG) biopsies in order to assess histological changes (Figure 2). Details are given in the study protocol (Supplementary Material).

The primary endpoint was the proportion of patients who had a ≥ 3 point reduction from baseline in the ESSDAI score after 12 weeks of treatment [21, 22]. Secondary endpoints were the mean differences from baseline at Week 12 for ESSDAI, ESSPRI, the Short Form-36 Health Survey (SF-36) mental and physical components, unstimulated tear production, and mechanically stimulated salivary flow [23-26]. Stimulated salivary flow was measured using mechanical stimulation. Unstimulated tear production rate was measured using the Schirmer method. Salivary and tear samples were also used for biomarker measurements. Soluble biomarkers (cathepsin S mass, cystatin C, B-cell activating factor [BAFF], and 4- β -hydroxycholesterol, desmosine, isodesmosine), as well as the changes from baseline in mean numbers of B-cells, T-cells and monocytes were estimated.

Safety assessments consisted of monitoring and recording AEs, including serious adverse events (SAEs) and non-serious AEs of special interest, monitoring of vital signs (systolic blood pressure, diastolic blood pressure, pulse rate), safety electrocardiograms (ECGs), and laboratory safety tests.

Statistical analysis

The sample size was calculated to detect a difference in ESSDAI response rates between treatment arms in the range of 25-33% (two-sided Chi-square test assuming $\alpha=0.05$ and placebo rate $\leq 25\%$). Seventy patients (35 per group) would provide approximately 70% power to detect a difference of 3 points between treatment arms in the change from baseline in ESSDAI score (t-test assuming two-sided $\alpha=0.05$ and standard deviation of 5.0). All efficacy outcomes were analyzed according to the modified intent-to-treat (mITT) principle. The mITT population

consisted of all patients who were randomized and who had received at least one dose of study drug.

The proportion of patients who had ≥ 3 -point reduction from baseline in ESSDAI score after 12 weeks of treatment were compared between the two treatment arms using a Pearson Chi-square test (two-sided p-values, $\alpha=0.05$). Secondary endpoints that were binary were analyzed with similar methods used for analyzing the primary endpoint. Continuous secondary endpoints were analyzed using a Mixed Model for Repeated Measures (MMRM) approach.

All patients who received at least one dose of the study medication were included in the safety analysis population.

RESULTS

Patient characteristics

Seventy-five patients were enrolled in 23 study centers in the US, UK, Poland, Portugal, France and Germany. Thirty-eight patients were randomized to RO5459072 treatment and 37 to placebo (Figure 1). Sixty-six (88.0%) completed treatment; nine patients discontinued from the study (Figure 1). All 75 randomized patients were included in the analyses of efficacy and safety.

Baseline characteristics of the patients were similar in both arms (Table 1). The median age was 54 years; the majority were female (68 [90.7%]). The proportion of males was slightly higher in RO5459072 arm (6 [15.8%] compared to 1 [2.7%] in the placebo arm). Positive ANA autoantibodies were detected in 62/75 participants (82.7%). ANA-negative patients had a statistically significant lower baseline IgG adjusted mean concentration than ANA-positive patients (-4.42 g/L; $p=0.0140$). Forty-three patients (57%) were positive for both anti-SSA/Ro and anti-SSB/La antibodies. The adjusted mean concentration (g/L) of IgG at baseline between anti-SSB-negative (13.61) and -positive patients (15.78) did not reach statistical significance ($p=0.1251$). The domains contributing to the total ESSDAI scores are shown in Supplementary Figures S1 and S2. As in other recent trials, the domains making the largest contribution were the articular, biological, glandular, constitutional and lymphadenopathy domains. The most frequently-used concomitant medications ($\geq 20\%$ of patients in each study arm) included analgesics (RO5459072: 11/38 [28.9%]; placebo: 2/37 [5.4%]) and antihistamines (RO5459072: 13/38 [34.2%]; placebo: 4/37 [10.8%]). The number of patients with ≥ 1 previous medical conditions was 35/37 (94.6%) in the placebo arm and 36/38 (94.7%) in the RO5459072 arm.

Efficacy

The proportion of patients showing an improvement in ESSDAI score at Week 12 was not significantly different between the RO5459072 and placebo arms (42.1% versus 37.8% respectively; Table 2 and Supplementary Figure S3).

There were no statistically significant differences between the RO5459072 and placebo arms for the secondary endpoints (Table 2 and Supplementary Figure S4). The difference in the mean change from baseline to Week 12 in ESSDAI scores between the two groups was -0.13 (95% CI: -2.04, 1.78; $p=0.8905$). No significant differences were seen in any of the

ESSDAI individual domains between baseline and Week 12 for both groups (results not shown).

There was no significant difference between the placebo and RO5459072 groups in the proportion of ESSPRI responders (defined as patients with ≥ 1 point reduction from baseline in ESSPRI score at Week 12; Table 2). No significant differences were seen in any of the ESSPRI individual domains (results not shown). No significant changes were seen in the SF-36 mental and physical component scores in either arm (Table 2).

The findings for unstimulated tear production and mechanically stimulated salivary flow likewise showed no significant differences. Although the RO5459072 group showed a smaller decline compared to the placebo group at Week 12 for unstimulated tear production, these differences were not statistically significant (Table 2). At Week 12, mechanically stimulated salivary flow in the RO5459072 group showed a slight (but non-significant) trend towards improvement over the placebo group (Table 2).

Soluble biomarkers

Cathepsin S mass is a direct marker of target engagement by RO5459072 [19] and there was an increase in the plasma concentration of cathepsin S over the dosing period in the RO5459072 arm (Figure 3). There was a 2.4-fold increase at Week 12 compared to baseline in the RO5459072 group, with mean (\pm SD) values ranging from 7.48 (\pm 1.91) ng/mL at baseline to 18.09 (\pm 4.71) ng/mL at Week 12. No change in cathepsin S mass was observed in the placebo group (results not shown). Throughout the study there were no changes in the levels of cystatin C, an endogenous antagonist of cathepsin S (results not shown).

There was a modest decrease in mean (\pm standard deviation [SD]) IgG levels of -0.50 (\pm 1.13) in the RO5459072 arm compared with 0.48 (\pm 1.78) in the placebo arm ($p=0.010$). Similar trends were seen for IgM with mean values of -0.17 (\pm 0.20) and 0.06 (\pm 0.25), respectively ($p<0.001$). There was a modest transient increase in the levels of the cytokine BAFF in the RO5459072 arm compared to the placebo arm, with the mean (\pm SD) value peaking at Week 2 at 1179.8 (\pm 354.4) pg/mL, compared to a baseline value of 1072.7 (\pm 323.2) pg/mL. In contrast, levels of BAFF remained stable throughout the treatment period in the placebo group (results not shown). However, these differences were not statistically significant in either arm.

Circulating white blood cells

There were modest changes in the levels of circulating white blood cells, including T-cells, B-cells, and monocytes; however, the differences between the study arms were not significant due to high individual variability.

There was a small transient decrease in the absolute numbers of circulating B-cells in the RO5459072 group, with a maximal reduction at Week 2 (mean [\pm SD] decrease of -20.3 [\pm 60.5] cells/ μ L). By comparison, the placebo group showed a mean (\pm SD) change from baseline to Week 2 of 4.7 (\pm 49.8) cells/ μ L. The mean (SD) of the absolute values was 202.4 (\pm 117.2) cells/ μ L at baseline and 197.5 (\pm 107.5) cells/ μ L at Week 12 in the placebo group; and 204.9 (\pm 114.0) cells/ μ L at baseline and 205.1 (\pm 132.3) cells/ μ L at Week 12 in the RO5459072 group.

A slight decrease was also seen in the absolute numbers of circulating CD8+ T-cells at the end of the treatment period (Week 12) in the RO5459072 group. The mean (\pm SD) change from baseline to Week 12 was -4.2 (\pm 97.3) cells/ μ L in the placebo group and -42.1 (\pm 149.9) cells/ μ L in the RO5459072 group. In contrast, no differences were observed in the numbers of circulating CD4+ T-cells in both study groups. The mean (\pm SD) change from baseline to Week 12 was 17.8 (\pm 197.3) cells/ μ L in the placebo group and 10 (\pm 188.9) cells/ μ L in the RO5459072 group.

For monocytes, there was a small increase in the absolute values over the dosing period in the RO5459072 group compared to the placebo group. The mean (\pm SD) change from baseline at Week 12 was -3.1 (\pm 107.8) cells/ μ L in the placebo group and 42.5 (\pm 80.6) cells/ μ L in the RO5459072 group.

Salivary gland biopsies

Thirty-five biopsy samples from 19 patients (19 samples) at baseline (8 in the placebo group and 11 in RO5459072 group) and 16 samples after 12 weeks' treatment (5 in the placebo group and 11 in the RO5459072 group) were processed for histological examination, including the change from baseline in focus score (number of lymphocytic foci per 4 mm²), mean foci area and percentage area of lymphocytic infiltration, and changes in the organization of lymphocytic foci. No significant differences in any of these parameters were observed in either arm (results not shown).

Safety

The mean (SD) total cumulative dose of RO5459072 in this study was 14,247.4 (5343.8) mg, with a mean duration of treatment of 73 days in the RO5459072 arm and 82 days in the placebo arm.

Overall, treatment with RO5459072 at 200 mg daily (administered as 100 mg BID) over 12 weeks was well-tolerated (Table 3). There was one death (cardiac arrest in a patient in the placebo group). Three patients reported SAEs: two patients in the placebo group had a total of three SAEs (headache, metabolic acidosis and the incident of cardiac arrest, which led to death) and one patient in the RO5459072 group had one SAE (iron deficiency anemia). No SAEs were considered related to study treatment. Six patients had AEs that led to withdrawal from study treatment (all in the RO5459072 group); none were considered serious. The Preferred Terms were: chest discomfort, limb discomfort, palpitations, peripheral swelling, headache, pain in jaw, rash, pruritus, urticaria, abdominal pain and diarrhea. Overall, the incidence of AEs was similar in both groups (Table 3). The majority of AEs were mild to moderate in severity. No obvious drug-related trends or signals were observed, and there were no clinically relevant changes in laboratory parameters, ECGs, or vital sign measurements.

DISCUSSION

The primary endpoint of this study, defined as the proportion of patients with a ≥ 3 point reduction in ESSDAI score after 12 weeks' treatment compared to baseline, was not met. The ESSDAI is a compound clinical scoring system that measures 12 domains which capture disease activity in Sjögren's syndrome [21, 23]. Although a mean reduction of ≥ 3 points was observed in around half of the RO5459072-treated patients, this response was unexpectedly matched by those in the placebo group. Similarly, no significant differences were observed in any of the individual ESSDAI domains. The high placebo responder rates could indicate the need to look at more rigorous cut-offs for ESSDAI response [27], although the absence of any difference in mean score over time makes a differential effect between the study arms unlikely.

Although the ESSDAI is widely used to measure disease activity in clinical studies, ensuring an accurate and reproducible rating of each domain remains a challenge [28]. The current means of scoring and weighting the 12 domains leaves much room for subjective scoring [28], thereby increasing the possibility of variance as we also observed, with a wide individual variation in ESSDAI results in both study arms. Furthermore, some individual domains, such as the one for the peripheral nervous system (PNS), may not have responded to treatment within the 12-week study period. Altogether, these factors may have contributed towards the study outcome.

In addition to the ESSDAI and ESSPRI, we also evaluated quality of life scores (SF-36 mental and physical components), unstimulated tear production, and mechanically stimulated salivary flow. The scores for both components of the SF-36 were similar between both study arms at the end of the treatment period. Both groups showed a decline in unstimulated tear production at Week 12 compared to baseline; however, the RO5459072 group showed less of a decline compared to the placebo group. At Week 12, the RO5459072 arm showed a slight trend towards improvement over the placebo arm with respect to mechanically stimulated salivary flow. However, the results for these secondary endpoints were not statistically significant.

Analysis of soluble biomarkers (including cathepsin S mass, cystatin C, 4- β -hydroxycholesterol, and BAFF) was performed at baseline and throughout the 12-week treatment period. Over the treatment period, we observed a 2.4-fold increase in the concentration of cathepsin S mass (relative to baseline) in the RO5459072 arm, reaching a plateau at Week 2 (Figure 3). These findings suggest direct target engagement between RO5459072 and cathepsin S in those patients who received the study drug. There was no

evidence of an increased endogenous inhibition effect as indicated by similar levels of plasma cystatin C, an endogenous antagonist of cathepsin S, in both study arms [29, 30].

Several other exploratory endpoints were measured in this study to assess the effect of RO5459072 on T-cell-dependent activation of B-cells. We observed a trend towards a modest and transient decrease in the number of B-cells in the RO5459072 group (at Week 2), and a small decrease in the number of CD8+ T-cells at Week 12. These observations are consistent with the expected effects of RO5459072 on MHC-II-mediated immune stimulation of adaptive T-cells and B-cells. No significant trends were observed in histological analyses of MSG biopsies. Given the lack of a clear signal for these parameters, our findings highlight the need for further studies to fully understand the mechanisms of MHC-II-mediated immune stimulation in pSjS.

There are several limitations to our study. First, there is no formal consensus on the optimal outcome for evaluating treatment efficacy in pSjS. Currently, the ESSDAI and ESSPRI are the only disease-specific validated clinical scores available for pSjS [22, 24]. Although the ESSPRI has an acceptable reproducibility, the scores do not necessarily correlate with systemic disease activity [31]. pSjS is characterized by considerable heterogeneity and its spectrum extends from secretory gland dysfunction to systemic involvement with extra-glandular manifestations. Thus, symptoms can range from mild sicca symptoms, pain, fatigue, and arthralgia to more severe systemic manifestations such as arthritis, vasculitis, or tubulointerstitial nephritis. The breadth and complexity of these symptoms pose a challenge for capturing treatment effect and disease outcomes. Not surprisingly, our results showed a wide variation across all of the study endpoints. These may be a reflection of the complexity of the disease, compounded by the difficulties in detecting small changes using the currently available clinical scores. The heterogeneity in disease manifestations and high placebo responses with individual measures, seen also in other recent large multi-center trials [32-34], has led to proposals for composite outcomes [35, 36]; however, these require further validation and were not available at the time this study was designed and analyzed. Other possible explanations for the high placebo responses seen include the use of concomitant medications, regression to the mean, and positive expectations given the lack of proven therapeutics in pSjS. Another uncertainty is the timeframe in which to detect a treatment effect. Many studies in pSjS have ranged in treatment duration between 6-24 weeks [37-40]; however, few studies have identified a clear treatment effect within these windows [33, 40-42]. Despite the changes seen in immunoglobulin levels in our study, it is uncertain if benefits in clinical or patient-reported outcomes would have been observed with a longer study timeframe. In other studies, a change

in immunoglobulins was not associated with symptomatic improvement after 24 weeks' treatment with hydroxychloroquine or abatacept [32, 37]. Finally, the small size of our study population precluded further analysis of the observed differences between the study arms.

Presentation of antigenic peptide by MHC-II expressed on the surfaces of antigen-presenting cells is central for adaptive immune responses and for autoimmune diseases mediated by CD4⁺ T-cells. Removal of the invariant chain bound to MHC-II is essential for both peptide loading and also for MHC-II to exit the endoplasmic reticulum for subsequent cell surface expression. Removal of the invariant chain is achieved by a number of proteolytic steps, the last being mediated by cathepsin S in B-cells and dendritic cells [19]. Cathepsin S inhibition would therefore be anticipated to have efficacy in CD4⁺ T-cell mediated autoimmune diseases and amelioration of disease in models of SLE, Sjogren's, inflammatory arthritis and multiple sclerosis has been observed [14, 17, 43, 44]. Despite this, RO5459072 has also failed to show efficacy in psoriasis [45] and another cathepsin S inhibitor was ineffective in rheumatoid arthritis [46].

RO5459072 was well tolerated in our study population, albeit 15.8% of the RO5459072 arm discontinued treatment or withdrew. One death was reported (due to cardiac arrest in a placebo patient). No apparent drug-related trends or signals emerged in terms of AEs, ECG, vital signs, and safety laboratory parameters.

CONCLUSIONS

The primary endpoint of this study, the proportion of patients showing an improvement in ESSDAI score (≥ 3 points from baseline to Week 12), was not met. RO5459072 was generally well-tolerated in patients with pSjS. Further work is needed to clarify the role of cathepsin S and MHC-II-mediated immune stimulation in pSjS.

TABLES

Table 1. Baseline characteristics of the study population.

	Placebo (N=37)	RO5459072 (N=38)	Both (N=75)
Age (years)			
Mean (SD)	52.3 (11.8)	52.1 (13.2)	52.2 (12.5)
Median	53.0	54.5	54.0
Min-max	30 - 73	21 - 75	21 - 75
Age group (years)			
<65	32 (86.5%)	32 (84.2%)	64 (85.3%)
≥65	5 (13.5%)	6 (15.8%)	11 (14.7%)
Gender			
Male	1 (2.7%)	6 (15.8%)	7 (9.3%)
Female	36 (97.3%)	32 (84.2%)	68 (90.7%)
Race			
Asian	1 (2.7%)	1 (2.6%)	2 (2.7%)
Black or African American	3 (8.1%)	2 (5.3%)	5 (6.7%)
Caucasian	33 (89.2%)	35 (92.1%)	68 (90.7%)
Ethnicity			
Hispanic or Latino	2 (5.4%)	0	2 (2.7%)
Non-Hispanic and non-Latino	35 (94.6%)	38 (100.0%)	73 (97.3%)
Country			
Germany	7 (18.9%)	6 (15.8%)	13 (17.3%)
France	4 (10.8%)	3 (7.9%)	7 (9.3%)
UK	1 (2.7%)	7 (18.4%)	8 (10.7%)
Poland	10 (27.0%)	9 (23.7%)	19 (25.3%)
Portugal	3 (8.1%)	3 (7.9%)	6 (8.0%)
US	12 (32.4%)	10 (26.3%)	22 (29.3%)
Weight (kg)			
Mean (SD)	71.98 (24.06)	72.46 (17.60)	72.23 (20.89)
Median	66.40	66.75	66.50
Min-max	50.0 - 172.0	48.0 - 111.0	48.0 - 172.0
Baseline ESSDAI scores			
Mean (SD)	11.27 (5.71)	11.79 (4.69)	-
Baseline ESSPRI scores			
Mean (SD)	7.34 (1.19)	6.98 (0.98)	-
Anti-SSA status, n (%)			
Positive	37 (100%)	38 (100%)	75 (100%)
Negative	0	0	0
Anti-SSB status, n (%)			
Positive	22 (59.5%)	18 (47.4%)	40 (53.3%)
Negative	15 (40.5%)	20 (52.6%)	35 (46.7%)
Rheumatoid factor status, n (%)			
Positive	18 (48.6%)	17 (44.7%)	35 (46.7%)
Negative	19 (51.4%)	21 (55.3%)	40 (53.3%)
IgG			
Mean (SD)	15.74 (6.77)	13.59 (4.92)	14.65 (5.96)
IgM			
Mean (SD)	1.24 (0.82)	1.26 (0.75)	1.25 (0.78)

	Placebo (N=37)	RO5459072 (N=38)	Both (N=75)
Baseline mechanically stimulated salivary flow rate, mL/min Mean (SD)	0.45 (0.29)	0.55 (0.58)	0.50 (0.46)
Baseline Schirmer's test for tear flow, mm/5 min Mean (SD)	7.53 (9.66)	7.84 (10.15)	7.69 (9.84)
Received methotrexate treatment (at least once)	6 (16.2%)	10 (26.3%)	16 (21.3%)
Received hydroxychloroquine medications (at least once)	16 (43.2%)	24 (63.2%)	40 (53.3%)
Received corticosteroid medications (at least once)	19 (51.4%)	17 (44.7%)	36 (48.0%)

Table 2. Primary and secondary efficacy outcomes at Week 12.

Endpoint	Placebo N=37	RO5459072 N=38
Primary efficacy endpoint		
ESSDAI responders 95% CI	14 (37.8%) (20.86, 54.82)	16 (42.1%) (25.09, 59.12)
ESSDAI response rate ^a Difference in response rates (95% CI) p-value	4.27 (-20.55, 29.08) 0.7955	
Secondary efficacy endpoints		
ESSPRI responders	21 (56.8%)	22 (57.9%)
ESSPRI response rate ^b Difference in response rates (95% CI) p-value	1.14 (-23.92, 26.19) 0.9877	
ESSDAI score Difference of adjusted means (95% CI) p-value	-0.13 (-2.04, 1.78) 0.8905	
ESSPRI score Difference of adjusted means (95% CI) p-value	-0.22 (-1.08, 0.64) 0.6077	
SF-36 Mental Difference of adjusted means (95% CI) p-value	-2.06 (-5.87, 1.75) 0.2846	
SF-36 Physical Difference of adjusted means (95% CI) p-value	-0.33 (-2.43, 3.08) 0.8134	
Unstimulated tear production Difference of adjusted means (95% CI) p-value	0.87 (-1.30, 3.03) 0.4266	
Mechanically stimulated salivary flow Difference of adjusted means (95% CI) p-value	0.06 (-0.21, 0.34) 0.6429	

CI, confidence interval; ESSDAI, EULAR Sjögren's Syndrome (SS) Disease Activity Index; ESSPRI, EULAR Sjögren's Syndrome (SS) Patient Reported Index; SF-36, Short Form 36 Health Survey.

Baseline is the patient's last observation prior to initiation of study drug.

^a Patients with ≥ 3 point reduction from baseline in ESSDAI at Week 12 were classified as responders.

^b Patients with ≥ 1 point reduction from baseline in ESSPRI at Week 12 were classified as responders.

Patients with a missing response were classed as non-responders.

Table 3. Overview of adverse events.

	Placebo (N=37)	RO5459072 (N=38)	All (N=75)
	n (%)		
Number of patients with ≥ 1 adverse event	29 (78.4%)	29 (76.3%)	58 (77.3%)
Total number of adverse events	68	113	181
Deaths	1 (2.7%)	0	1 (1.3%)
Withdrawals from the study due to an adverse event	0	6 (15.8%)	6 (8.0%)
Number of patients with ≥ 1 :			
Adverse event with fatal outcome	1 (2.7%)	0	1 (1.3%)
Serious adverse event	2 (5.4%)	1 (2.6%)	3 (4.0%)
Serious adverse event leading to withdrawal from treatment	0	0	0
Serious adverse event leading to dose modification/ treatment interruption	0	0	0
Related serious adverse event	0	0	0
Adverse event leading to withdrawal from treatment	0	6 (15.8%)	6 (8.0%)
Adverse event leading to dose modification/ treatment interruption	1 (2.7%)	5 (13.2%)	6 (8.0%)
Related adverse event	8 (21.6%)	20 (52.6%)	28 (37.3%)
Related adverse event leading to withdrawal from treatment	0	5 (13.2%)	5 (6.7%)
Related adverse event leading to dose modification/ treatment interruption	1 (2.7%)	5 (13.2%)	6 (8.0%)

Adverse events were encoded using MedDRA version 20.0. Multiple occurrences of the same adverse event in one individual were counted only once except for within the “Total number of adverse events” row, in which multiple occurrences of the same adverse event were counted separately.

FIGURES

Figure 1. Flow chart of inclusion in the study.

Figure 2. Overview of study design.

BL, baseline; MSG, minor salivary gland

Figure 3. Concentration of plasma cathepsin S mass over the treatment period.

Supplementary Figure S1. Breakdown of ESSDAI scores at baseline (ITT population)

Study arm

(PBO, placebo; 100 mg, RO5459072 100 mg BID)

Study arm

(PBO, placebo; 100 mg, RO5459072 100 mg BID)

CNS, central nervous system; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index; ITT, intent-to-treat; PNS, peripheral nervous system.

Supplementary Figure S2. Mean plot of ESSDAI scores at baseline (ITT population)

CNS, central nervous system; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index; ITT, intent-to-treat; PNS, peripheral nervous system.

Supplementary Figure S3. Adjusted Mean Plot of Change from Baseline in ESSDAI (mITT Population).

Negative change represents an improvement.

Supplementary Figure S4. Adjusted Mean Plot of Change from Baseline in ESSPRI (mITT Population).

Adjusted Mean Plot of change from baseline in ESSPRI, Modified Intent-to-Treat Patients
Protocol: BP30037

Negative change represents an improvement.
