ABSTRACT

Background

Early accurate detection of all skin cancer types is essential to guide appropriate management and to improve morbidity and survival. Melanoma and squamous cell carcinoma (SCC) are high-risk skin cancers which have the potential to metastasise and ultimately lead to death, whereas basal cell carcinoma (BCC) is usually localised with potential to infiltrate and damage surrounding tissue. Anxiety around missing early curable cases needs to be balanced against inappropriate referral and unnecessary excision of benign lesions. Teledermatology provides a way for generalist clinicians to access the opinion of a specialist dermatologist for skin lesions that they consider to be suspicious without referring the patients through the normal referral pathway. Teledermatology consultations can be 'store-and-forward' with electronic digital images of a lesion sent to a dermatologist for review at a later time, or can be live and interactive consultations using videoconferencing to connect the patient, referrer and dermatologist in real time.

Objectives

To determine the diagnostic accuracy of teledermatology for the detection of any skin cancer (melanoma, BCC or cutaneous squamous cell carcinoma (cSCC)) in adults, and to compare its accuracy with that of in-person diagnosis.

Search methods

We undertook a comprehensive search of the following databases from inception up to August 2016: Cochrane Central Register of Controlled Trials, MEDLINE, Embase, CINAHL, CPCI, Zetoc, Science Citation Index, US National Institutes of Health Ongoing Trials Register, NIHR Clinical Research Network Portfolio Database and the World Health Organization International Clinical Trials Registry Platform. We studied reference lists and published systematic review articles.

Selection criteria

Studies evaluating skin cancer diagnosis for teledermatology alone, or in comparison with face-to-face diagnosis by a specialist clinician, compared with a reference standard of histological confirmation or clinical follow-up and expert opinion. We also included studies evaluating the referral accuracy of teledermatology compared with a reference standard of face-to-face diagnosis by a specialist clinician.

Data collection and analysis

Two review authors independently extracted all data using a standardised data extraction and quality assessment form (based on QUADAS-2). We contacted authors of included studies where there was information related to the target condition of any skin cancer missing. Data permitting, we estimated summary sensitivities and specificities using the bivariate hierarchical model. Due to the scarcity of data, we undertook no covariate investigations for this review. For illustrative purposes, we plotted estimates of sensitivity and specificity on coupled forest plots for diagnostic threshold and target condition under consideration.

Main results

The review included 22 studies reporting diagnostic accuracy data for 4057 lesions and 879 malignant cases (16 studies) and referral accuracy data for reported data for 1449 lesions and 270 'positive' cases as determined by the reference standard face-to-face decision (six studies). Methodological quality was variable with poor reporting hindering assessment. The overall risk of bias was high or unclear for participant selection, reference standard, and participant flow and timing in at least half of all studies; the majority were at low risk of bias for the index test. The applicability of study findings were of high or unclear concern for most studies in all domains assessed due to the recruitment of participants from secondary care settings or specialist clinics rather than from primary or community-based settings in which teledermatology is more likely to be used and due to the acquisition of lesion images by dermatologists or in specialist imaging units rather than by primary care clinicians.

Seven studies provided data for the primary target condition of any skin cancer (1588 lesions and 638 malignancies). For the correct diagnosis of lesions as malignant using photographic images, summary sensitivity was 94.9% (95% confidence interval (CI) 90.1% to 97.4%) and summary specificity was 84.3% (95% CI 48.5% to 96.8%) (from four studies). Individual study estimates using dermoscopic images or a combination of photographic and dermoscopic images generally suggested similarly high sensitivities with highly variable specificities. Limited comparative data suggested similar diagnostic accuracy between teledermatology assessment and in-person diagnosis by a dermatologist; however, data were too scarce to draw firm conclusions. For the detection of invasive melanoma or atypical intraepidermal melanocytic variants both sensitivities and specificities were more variable. Sensitivities ranged from 59% (95% CI 42% to 74%) to 100% (95% CI 48% to 100%) and specificities from 30% (95% CI 22% to 40%) to 100% (95% CI 93% to 100%), with reported diagnostic thresholds including the correct diagnosis of melanoma, classification of lesions as 'atypical' or 'typical', and the decision to refer or to excise a lesion.

Referral accuracy data comparing teledermatology against a face-to-face reference standard suggested good agreement for lesions considered to require some positive action by face-to-face assessment (sensitivities of over 90%). For lesions considered of less concern when assessed face-to-face (e.g. for lesions not recommended for excision or referral), agreement was more variable with teledermatology specificities ranging from 57% (95% CI 39% to 73%) to 100% (95% CI 86% to 100%), suggesting that remote assessment is more likely to recommend excision, referral or follow-up compared to in-person decisions.

Authors' conclusions

Studies were generally small and heterogeneous and methodological quality was difficult to judge due to poor reporting. Bearing in mind concerns regarding the applicability of study participants and of lesion image acquisition in specialist settings, our results suggest that teledermatology can correctly identify the majority of malignant lesions. Using a more widely defined threshold to identify 'possibly' malignant cases or lesions that should be considered for excision is likely to appropriately triage those lesions requiring face-to-face assessment by a specialist. Despite the increasing use of teledermatology on an international level, the evidence base to support its ability to accurately diagnose lesions and to triage lesions from primary to secondary care is lacking and further prospective and pragmatic evaluation is needed.

PLAIN LANGUAGE SUMMARY

What is the diagnostic accuracy of teledermatology for the diagnosis of skin cancer in adults?

Why is improving the diagnosis of skin cancer important?

There are different types of skin cancer. Melanoma is one of the most dangerous forms and it is important to identify it early so that it can be removed. If it is not recognised when first brought to the attention of doctors (also known as a false-negative test result) treatment can be delayed resulting in the melanoma spreading to other organs in the body and possibly causing early death. Cutaneous squamous cell carcinoma (cSCC) and basal cell carcinoma (BCC) are usually localised skin cancers, although cSCC can spread to other

parts of the body and BCC can cause disfigurement if not recognised early. Calling something a skin cancer when it is not really a skin cancer (a false-positive result) may result in unnecessary surgery and other investigations that can cause stress and worry to the patient. Making the correct diagnosis is important. Mistaking one skin cancer for another can lead to the wrong treatment being used or lead to a delay in effective treatment.

What is the aim of the review?

The aim of this Cochrane Review was to find out whether teledermatology is accurate enough to identify which people with skin lesions need to be referred to see a specialist dermatologist (a doctor concerned with disease of the skin) and who can be safely reassured that their lesion (damage or change of the skin) is not malignant. We included 22 studies to answer this question.

What was studied in the review?

Teledermatology means sending pictures of skin lesions or rashes to a specialist for advice on diagnosis or management. It is a way for primary care doctors (general practitioners (GPs)) to get an opinion from a specialist dermatologist without having to refer patients through the normal referral pathway. Teledermatology can involve sending photographs or magnified images of a skin lesion taken with a special camera (dermatoscope) to a skin specialist to look at or it might involve immediate discussion about a skin lesion between a GP and a skin specialist using videoconferencing.

What are the main results of the review?

The review included 22 studies, 16 studies comparing teledermatology diagnoses to the final lesion diagnoses (diagnostic accuracy) for 4057 lesions and 879 malignant cases and five studies comparing teledermatology decisions to the decisions that would be made with the patient present (referral accuracy) for 1449 lesions and 270 'positive' cases.

The studies were very different from each other in terms of the types of people with suspicious skin cancer lesions included and the type of teledermatology used. A single reliable estimate of the accuracy of teledermatology could not be made. For the correct diagnosis of a lesion to be a skin cancer, data suggested that less than 7% of malignant skin lesions were missed by teledermatology. Study results were too variable to tell us how many people would be referred unnecessarily for a specialist dermatology appointment following a teledermatology consultation. Without access to teledermatology services however, most of the lesions included in these studies would likely be referred to a dermatologist.

How reliable are the results of the studies of this review?

In the included studies, the final diagnosis of skin cancer was made by lesion biopsy (taking a small sample of the lesion so it could be examined under a microscope) and the absence of skin cancer was confirmed by biopsy or by follow-up over time to make sure the skin lesion remained negative for melanoma. This is likely to have been a reliable method for deciding whether people really had skin cancer. In a few studies, a diagnosis of no skin cancer was made by a skin specialist rather than biopsy. This is less likely to have been a reliable method for deciding whether people really had skin cancer*. Poor reporting of what was done in the study made it difficult for us to say how reliable the study results are. Selecting some patients from specialist clinics instead of primary care along with different ways of doing teledermatology were common problems.

Who do the results of this review apply to?

Studies were conducted in: Europe (64%), North America (18%), South America (9%) or Oceania (9%). The average age of people who were studied was 52 years; however, several studies included at least some people under the age of 16 years. The percentage of people with skin cancer ranged between 2% and 88% with an average of 30%, which is much higher than would be observed in a primary care setting in the UK.

What are the implications of this review?

Teledermatology is likely to be a good way of helping GPs to decide which skin lesions need to be seen by a skin specialist. Our review suggests that using magnified images, in addition to photographs of the lesion, improves accuracy. More research is needed to establish the best way of providing teledermatology services.

How up-to-date is this review?

The review authors searched for and used studies published up to August 2016.

*In these studies, biopsy, clinical follow-up or specialist clinician diagnosis were the reference comparisons.

SUMMARY OF FINDINGS FOR THE MAIN COMPARISON *[Explanation]*

Question:	What is the diagnostic accuracy of teledermatology for the detection of skin cancer in adults?		
Population:	Adults with lesions suspicious for skin cancer		
Index test:	TD using photographic or dermoscopic (or both) images		
Comparator test:	Face-to-face diagnosis using visual inspection or dermoscopy (or both)		
Target condition:	Any skin cancer, including invasive melanoma and atypical intraepidermal melanocytic variants, BCC and cSCC		
Reference standard:	Histology with or without long-term follow-up (diagnostic accuracy); expert face-to-face diagnosis (for referral accuracy)		
Action:	If accurate, positive results ensure the malignant lesions are not missed but are appropriately referred for specialist assessment or are treated appropriately in a non-referred setting, and those with negative results can be safely reassured and discharged		
Quantity of evidence	Number of studies	Total lesions	Total cases
Diagnostic accuracy	16	4057	879
Referral accuracy	6	1449	270
Limitations			
Risk of bias:	Low risk for participant selection in 7 studies; high risk (5) from case-control design (2) or inappropriate exclusion criteria (4). Low risk for teledermatology assessments (22). Low risk for comparison with face-to-face diagnosis (2/5); unclear (3). Low risk for reference standard (10/22); high risk from use of expert diagnosis alone - referral accuracy (6) or inadequate reference standard (6). High risk for participant flow (17) due to differential verification (5), and exclusions following recruitment (14); timing of tests not mentioned in 14 studies		
Applicability of evidence to question:	High concern (14/22) for applicability of participants due to recruitment from secondary care or specialist clinics (12) or inclusion of multiple lesions per participant (6). High concern for applicability of teledermatology assessments (12/22) due to images acquired by dermatologists secondary care settings or in medical imaging units rather than images acquired in primary care. Low concern for reference standard (6/22); unclear concern due to lack of information concerning the expertise of the histopathologist (13) or expert face-to-face diagnosis (3)		

Findings:			
<p>7 studies reported diagnostic accuracy data for the primary target condition of any skin cancer; 9 studies for the detection of invasive melanoma or atypical intraepidermal melanocytic variants; 2 studies for invasive melanoma alone; and 4 studies for BCC alone. 6 studies reported only referral accuracy data (teledermatology decisions versus face-to-face decisions). The findings presented are based on results for the primary target condition of any skin cancer and for the detection of invasive melanoma or atypical intraepidermal melanocytic variants</p>			
Diagnostic accuracy data	Number of datasets	Total lesions	Total malignant
Test: TD using photographic images for any skin cancer	4	717	452
	3 studies reported a cross-tabulation of lesion final diagnoses against the diagnosis on teledermatology such that data could be extracted for the detection of any malignancy, regardless of any misclassification of 1 skin cancer for another, e.g. a BCC diagnosed as a melanoma or vice versa; and 1 study presented data for the detection of 'malignant' versus benign cases with no breakdown of individual lesion diagnoses given. Summary sensitivity was 94.9% (95% CI 90.1% to 97.4%) and summary specificity 84.3% (95% CI 48.5% to 96.8%). 2 studies providing a direct comparison between TD assessment and in-person diagnosis by a dermatologist the data suggested similar accuracy between approaches; however, data were too scarce to draw firm conclusions		
Test: TD using clinical and dermoscopic images for any skin cancer	3	928	215
	Sensitivities were 100% in all 3 studies. Specificities ranged from 25% (95% CI 5% to 57%) to 92% (95% CI 74% to 99%). Studies used varying thresholds to decide test positivity and included highly selected populations. No statistical pooling was undertaken		
Test: TD using photographic images for invasive melanoma or atypical intraepidermal melanocytic variants	4	1834	106
	Sensitivities ranged from 59% (95% CI 42% to 74%) to 100% (95% CI 48% to 100%) and specificities from 30% (95% CI 22% to 40%) to 100% (95% CI 93% to 100%). Diagnostic thresholds were correct diagnosis of melanoma (3) or classification as 'atypical' or 'typical.' Populations also varied, some including only atypical or higher-risk pigmented lesions and excluding equivocal lesions and others including both pigmented and non-pigmented lesions who were either self-referred or were deemed to require lesion excision. The number of melanomas missed ranged from 0 to 17		
Test: TD using photographic and dermoscopic images for invasive melanoma or atypical intraepidermal melanocytic variants	4	664	93

	Summary estimates were 85.4% (95% CI 68.3% to 94.1%) for sensitivity and 91.6% (95% CI 81.1% to 96.5%) for specificity. Sensitivities were lower for the correct diagnosis of melanoma (71% to 81%) compared to the decision to refer or to excise a lesion (96% to 100%). The number of melanomas missed ranged from 0 to 7		
All data (referral accuracy)	6	1449	270
	TD diagnoses were reported based on photographic images alone (4), photographic and dermoscopic images (1) and using live-link TD (1). Diagnostic decisions on TD varied, including the diagnosis of malignancy, the decision to excise a lesion, the decision to refer versus not refer, or to excise or follow-up at a later date. For store-and-forward TD sensitivities were generally above 90% indicating good agreement between remote image-based decisions with the face-to-face reference standard for lesions considered to require some positive action by face-to-face assessment. Specificities were more variable ranging from 57% (95% CI 39% to 73%) to 100% (95% CI 86% to 100%) suggesting that remote assessment is more likely to recommend excision, referral or follow-up for lesions considered of less concern when assessed face-to-face		

BCC: basal cell carcinoma; CI: confidence interval; cSCC: cutaneous squamous cell carcinoma; TD: teledermatology.

BACKGROUND

This review is one of a series of Cochrane Diagnostic Test Accuracy (DTA) reviews on the diagnosis and staging of melanoma and keratinocyte skin cancers conducted for the National Institute for Health Research (NIHR) Cochrane Systematic Reviews Programme. For the purposes of these reviews, diagnostic accuracy is assessed by the sensitivity and specificity of a test. [Appendix 1](#) shows the content and structure of the programme, [Appendix 2](#) provides a glossary of terms used.

Target condition being diagnosed

There are three main forms of skin cancer. Melanoma has the highest skin cancer mortality ([Cancer Research UK 2017](#)); however, the most common skin cancers in Caucasian populations are those arising from keratinocytes: basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC) ([Gordon 2013](#); [Madan 2010](#)). In 2003, the World Health Organization estimated that between two and three million 'non-melanoma' skin cancers (of which BCC is estimated to account for around 80% and cSCC around 16% of cases) and 132,000 melanoma skin cancers occur globally each year ([WHO 2003](#)).

In this DTA review there are three target conditions of interest melanoma, BCC and cSCC.

Melanoma

Melanoma arises from uncontrolled proliferation of melanocytes - the epidermal cells that produce pigment or melanin. Cutaneous melanoma refers to any skin lesion with malignant melanocytes present in the dermis, primarily including superficial spreading, nodular, acral lentiginous and lentigo maligna melanoma variants (see [Figure 1](#)). Melanoma in situ refers to abnormal melanocytes that are contained within the epidermis and have not yet invaded the dermis, but are at risk of progression to melanoma if left untreated. Lentigo maligna, a subtype of melanoma in situ in chronically sun-damaged skin, denotes another form of proliferation of abnormal melanocytes. Melanoma in situ and lentigo maligna are both atypical intraepidermal melanocytic variants. All forms of melanoma in situ can progress to invasive melanoma if growth breaches the dermo-epidermal junction during a vertical growth phase; however, malignant transformation is both lower and slower for lentigo maligna than for melanoma in situ ([Kasprzak 2015](#)). Melanoma is one of the most dangerous forms of skin cancer, with the potential to metastasise to other parts of the body via the lymphatic system and bloodstream. It accounts for only a small percentage of skin cancer cases but is responsible for up to 75% of skin cancer deaths ([Boring 1994](#); [Cancer Research UK 2017](#)).

Figure 1. Sample photograph of superficial spreading melanoma(left), basal cell carcinoma (centre) and squamous cell carcinoma (right). Copyright © 2012 Dr Rubeta Matin: reproduced with permission.

The incidence of melanoma rose to over 200,000 newly diagnosed cases worldwide in 2012 ([Erdmann 2013](#); [Ferlay 2015](#)), with an estimated 55,000 deaths ([Ferlay 2015](#)). The highest incidence was observed in Australia with 13,134 new cases of melanoma of the skin in 2014 ([ACIM 2017](#)), and in New Zealand with 2341 registered cases in 2010 ([HPA and MelNet NZ 2014](#)). In the USA, the predicted incidence in 2014 was 73,870 per annum and the

predicted number of deaths was 9940 ([Siegel 2015](#)). The highest rates in Europe are in north-western Europe and the Scandinavian countries, with the highest incidence reported in Switzerland of 25.8 per 100,000 people in 2012. Rates in the England have tripled from 4.6 and 6.0 per 100,000 in men and women respectively, in 1990, to 18.6 and 19.6 per 100,000 in 2012 ([EUCAN 2012](#)). Indeed, in the UK, melanoma has one of the fastest ris-

ing incidence rates of any cancer, with the biggest projected increase in incidence between 2007 and 2030 (Mistry 2011). In the decade leading up to 2013, age-standardised incidence increased by 46%, with 14,500 new cases in 2013 and 2459 deaths in 2014 (Cancer Research UK 2017). Rates are higher in women than in men; however, the rate of incidence in men is increasing faster than in women (Arnold 2014). The rising incidence in melanoma is thought to be primarily related to an increase in recreational sun exposure and tanning bed use and an increasingly ageing population with higher lifetime recreational ultraviolet (UV) exposure, in conjunction with possible earlier detection (Belbasis 2016; Linos 2009). Belbasis 2016 provides a detailed review of putative risk factors, including eye and hair colour, skin type and density of freckles, history of melanoma, sunburn and presence of particular lesion types.

A database in the USA of over 40,000 patients from 1998 onwards, which assisted the development of the 8th American Joint Committee on Cancer (AJCC) Staging System indicated a five-year survival of 97% to 99% for stage I melanoma, which dropped to 32% to 93% in stage III disease depending on tumour thickness, the presence of ulceration and number of involved nodes (Gershenwald 2017). While these are substantial increases relative to survival in 1975 (Cho 2014), increasing incidence between 1975 and 2010 means that mortality rates have remained static during the same period. This observation, coupled with increasing incidence of localised disease, suggests that improved survival rates may be due to earlier detection and heightened vigilance (Cho 2014). New targeted therapies for advanced (stage IV), melanoma (e.g. BRAF inhibitors), have improved survival, and immunotherapies are evolving such that long-term survival is being documented (Pasquali 2018; Rozeman 2017). No new data regarding the survival prospects for patients with stage IV disease were analysed for the AJCC 8 staging guidelines due to lack of contemporary data (Gershenwald 2017).

Basal cell carcinoma

BCC can arise from multiple stem cell populations, including from the bulge and interfollicular epidermis (Grachtchouk 2011). BCC growth is usually localised, but it can infiltrate and damage surrounding tissue, sometimes causing considerable destruction and disfigurement, particularly when located on the face (Figure 1). The four main subtypes of BCC are superficial, nodular, morpheaic or infiltrative, and pigmented. They typically present as slow-growing asymptomatic papules, plaques or nodules which may bleed or form ulcers that do not heal (Firnhaber 2012). People with a BCC often present to healthcare professionals with a non-healing lesion rather than specific symptoms such as pain. Many lesions are diagnosed incidentally (Gordon 2013).

BCC most commonly occurs on sun-exposed areas on the head and neck (McCormack 1997), and they are more common in men and in people over the age of 40. Different authors have attributed a rising incidence of BCC in younger people to increased recre-

ational sun exposure (Bath-Hextall 2007a; Gordon 2013; Musah 2013). Other risk factors include Fitzpatrick skin types I and II (Fitzpatrick 1975; Lear 1997; Maia 1995); previous skin cancer history; immunosuppression; arsenic exposure; and genetic predisposition, such as in basal cell naevus (Gorlin's) syndrome (Gorlin 2004; Zak-Prelich 2004). Annual incidence is rising worldwide; Europe has experienced a mean increase of 5.5% per year since the late 1970s, the USA 2% per year, while estimates for the UK show incidence appears to be increasing more steeply at a rate of an additional 6 per 100,000 people per year (Lomas 2012). The rising incidence has been explained by an ageing population; changes in the distribution of known risk factors, particularly UV radiation; and improved detection due to the increased awareness among both practitioners and the general population (Verkouteren 2017). Hoorens 2016 points to evidence for a gradual increase in the size of BCCs over time, with delays in diagnosis ranging from 19 to 25 months.

According to National Institute for Health and Care Excellence (NICE) guidance (NICE 2010), low-risk BCCs are nodular lesions occurring in people older than 24 years who are not immunosuppressed and do not have Gorlin syndrome. Furthermore, they should be located below the clavicle; should be small (diameter of less than 1 cm) with well-defined margins; not recurrent following incomplete excision; and not in awkward or highly visible locations (NICE 2010). Superficial BCCs are also typically low risk and may be amenable to medical treatments such as photodynamic therapy (PDT) or topical chemotherapy (Kelleners-Smeets 2017). Assigning BCCs as low or high risk influences the management options (Batra 2002; Randle 1996).

Advanced locally destructive BCC can be found on 'high-risk' anatomical areas such as the eyebrow, eyelid, nose, ear and temple (these are at higher risk of invisible spread and therefore are more at risk of being incompletely excised (Baxter 2012; Lear 2014)), and they can arise from long-standing untreated lesions or from a recurrence of aggressive BCC after primary treatment (Lear 2012). Very rarely, BCC metastasises to regional and distant sites resulting in death, especially cases of large neglected lesions in people who are immunosuppressed or those with Gorlin syndrome (McCusker 2014). Rates of metastasis are reported at 0.0028% to 0.55% (Lo 1991), with very poor survival rates. It is recognised that basosquamous carcinoma (more like a high-risk SCC in behaviour and not considered a true BCC) is likely to have accounted for many cases of apparent metastases of BCC hence the spuriously high reported incidence in some studies of up to 0.55% which is not seen in clinical practice (Garcia 2009).

Squamous cell carcinoma of the skin

Primary cSCC arises from the keratinocytes of the outermost layer (epidermis) of the skin. People with cSCC often present with an ulcer or firm (indurated) papule, plaque or nodule (Firnhaber 2012; Griffin 2016), often with an adherent crust and poorly

defined margins (Madan 2010). This type of carcinoma can arise in the absence of a precursor lesion or it can develop from pre-existing actinic keratosis or Bowen's disease (considered by some clinicians to be squamous cell carcinoma in situ); the estimated annual risk of progression being less than 1% to 20% for newly arising lesions (Alam 2001), and 5% for pre-existing lesions (Kao 1986). It remains locally invasive for a variable length of time, but it has the potential to spread to the regional lymph nodes or via the bloodstream to distant sites, especially in immunosuppressed individuals (Lansbury 2010). High-risk lesions are those arising on the lip or ear, recurrent cSCC, lesions arising on non-exposed sites, scars or chronic ulcers, tumours more than 20 mm in diameter and with depth of invasion more than 4 mm, and poor differentiation on pathological examination (Motley 2009). Perineural invasion of nerves at least 0.1 mm in diameter is a further documented risk factor for high-risk cSCC (Carter 2013).

Chronic ultraviolet light exposure through recreation or occupation is strongly linked to cSCC occurrence (Alam 2001). It is particularly common in people with fair skin and in less common genetic disorders of pigmentation, such as albinism, xeroderma pigmentosum and recessive dystrophic epidermolysis bullosa (Alam 2001). Other recognised risk factors include immunosuppression; chronic wounds; arsenic or radiation exposure; certain drug treatments, such as voriconazole and BRAF mutation inhibitors; and previous skin cancer history (Baldursson 1993; Chowdri 1996; Dabski 1986; Fasching 1989; Lister 1997; Maloney 1996; O'Gorman 2014). In solid organ transplant recipients, cSCC is the most common form of skin cancer; the risk of developing cSCC has been estimated at 65 to 253 times that of the general population (Hartevelt 1990; Jensen 1999; Lansbury 2010). Overall, local and metastatic recurrence of cSCC at five years is estimated at 8% and 5% respectively (Rowe 1992). The five-year survival rate of metastatic cSCC of the head and neck is around 60% (Moeckelmann 2018).

Treatment

For primary melanoma, the mainstay of definitive treatment is wide local surgical excision of the lesion, to remove both the tumour and any malignant cells that might have spread into the surrounding skin (Garbe 2016; Marsden 2010; NICE 2015a; SIGN 2017; Sladden 2009). Recommended lateral surgical margins vary according to tumour thickness (Garbe 2016), and to stage of disease at presentation (NICE 2015a).

Treatment options for BCC and cSCC include surgery, other destructive techniques such as cryotherapy or electrodesiccation and topical chemotherapy. A Cochrane Review of 27 randomised controlled trials (RCTs) of interventions for BCC found very little good-quality evidence for any of the interventions used (Bath-Hextall 2007b). Complete surgical excision of primary BCC has a reported five-year recurrence rate of less than 2% (Griffiths 2005; Walker 2006), leading to significantly fewer recurrences

than treatment with radiotherapy (Bath-Hextall 2007b). After apparent clear histopathological margins (serial vertical sections) after standard excision biopsy with 4 mm surgical peripheral margins taken there is a five-year reported recurrence rate of around 4% (Drucker 2017). Mohs micrographic surgery, whereby surgeons microscopically examine horizontal sections of the tumour perioperatively, undertaking re-excision until the margins are tumour-free, are options for high-risk lesions on the face where standard wider excision margins might lead to incomplete excision or considerable functional impairment (Bath-Hextall 2007b; Lansbury 2010; Motley 2009; Stratigos 2015). Bath-Hextall 2007b found one trial comparing Mohs micrographic surgery with a 3 mm surgical margin excision in BCC (Smeets 2004); the update of this study showed non-significantly lower recurrence at 10 years with Mohs micrographic surgery (4.4% with Mohs micrographic surgery compared to 12.2% after surgical excision; $P = 0.10$) (van Loo 2014).

The main treatments for high-risk BCC are standard surgical excision, Mohs micrographic surgery or radiotherapy. For low-risk or superficial subtypes of BCC, or for people with small or multiple (or both) BCCs at low-risk sites (Marsden 2010), destructive techniques other than excisional surgery may be used (e.g. electrodesiccation and curettage or cryotherapy (Alam 2001; Bath-Hextall 2007b)). Alternatively, non-surgical ('non-destructive') treatments may be considered (Bath-Hextall 2007b; Drew 2017; Kim 2014), including topical chemotherapy such as imiquimod (Williams 2017), 5-fluorouracil (Arits 2013), ingenol mebutate (Nart 2015), and photodynamic therapy (PDT) (Roozeboom 2016). Non-surgical treatments are most frequently used for superficial forms of BCC, with one head-to-head trial suggesting topical imiquimod is superior to PDT and 5-fluorouracil (Jansen 2018). Although non-surgical approaches are increasingly used, they do not allow histological confirmation of tumour clearance, and their efficacy is dependent on accurate characterisation of the histological subtype and depth of tumour. The 2007 Cochrane review of BCC interventions found limited evidence from very small RCTs for these approaches (Bath-Hextall 2007b), which have only partially been addressed by subsequent studies (Bath-Hextall 2014; Kim 2014; Roozeboom 2012). Most BCC trials have compared interventions within the same treatment class, and few have compared medical versus surgical treatments (Kim 2014).

Vismodegib, a first-in-class Hedgehog signalling pathway inhibitor is now available for the treatment of metastatic or locally advanced BCC based on the pivotal study ERIVANCE BCC (Sekulic 2017). It is licensed for use in these patients where surgery or radiotherapy is inappropriate, e.g. for treating locally advanced periocular and orbital BCCs with orbital salvage of patients who otherwise would have required exenteration (Wong 2017). However, NICE has recommended against the use of vismodegib based on cost effectiveness and uncertainty of evidence (NICE 2017). A systematic review of interventions for primary cSCC found only one RCT eligible for inclusion (Lansbury 2010). Current practice

therefore relies on evidence from observational studies, as reviewed in [Lansbury 2013](#), for example. Surgical excision with predetermined margins is usually the first-line treatment ([Motley 2009](#); [Stratigos 2015](#)). Estimates of recurrence after Mohs micrographic surgery, surgical excision or radiotherapy, which are likely to have been evaluated in higher-risk populations, have shown pooled recurrence rates of 3%, 5.4% and 6.4%, respectively, with overlapping confidence intervals (CI); the review authors advised caution when comparing results across treatments ([Lansbury 2013](#)).

Index test(s)

Teledermatology is a term used to describe the delivery of dermatological care through information and communication technology ([Bashshur 2015](#)). It uses imaging modalities to provide specialist dermatology services either to other healthcare professionals (such as general practitioners (GP)), or to patients directly ([Ndegwa 2010](#)). It is considered a valuable tool in the diagnosis and management of skin disease, because of the visual nature of skin lesions and rashes ([Warshaw 2011](#)). Teledermatology allows an increased information flow between primary care physicians and dermatologists, which could lead to a reduction in waiting times and limit unnecessary referrals ([Ndegwa 2010](#); [Warshaw 2011](#); [Bashshur 2015](#)). In rural areas, where access to speciality services can have significant and potentially off-putting travel and time implications for the patient, teledermatology has the potential to widen access to specialist opinion.

Teledermatology consultations can be conducted in two main ways, store-and-forward or 'asynchronous,' and live interactive or 'synchronous' ([Ndegwa 2010](#)). With the store-and-forward approach, clinicians and patients are separated by both time and space, as electronic digital images are taken and then transmitted to a dermatologist for review at a later unspecified time ([Warshaw 2011](#)). The pictures can be digital photographic (or 'macroscopic') images, or can be magnified dermoscopic images taken using a dermatoscope. Images are often accompanied by a summary of the patient history and demographic information as part of a consultation package ([Ndegwa 2010](#)). Furthermore, recent developments in smartphone technology have also introduced a new platform for transferring lesion images from one setting to another

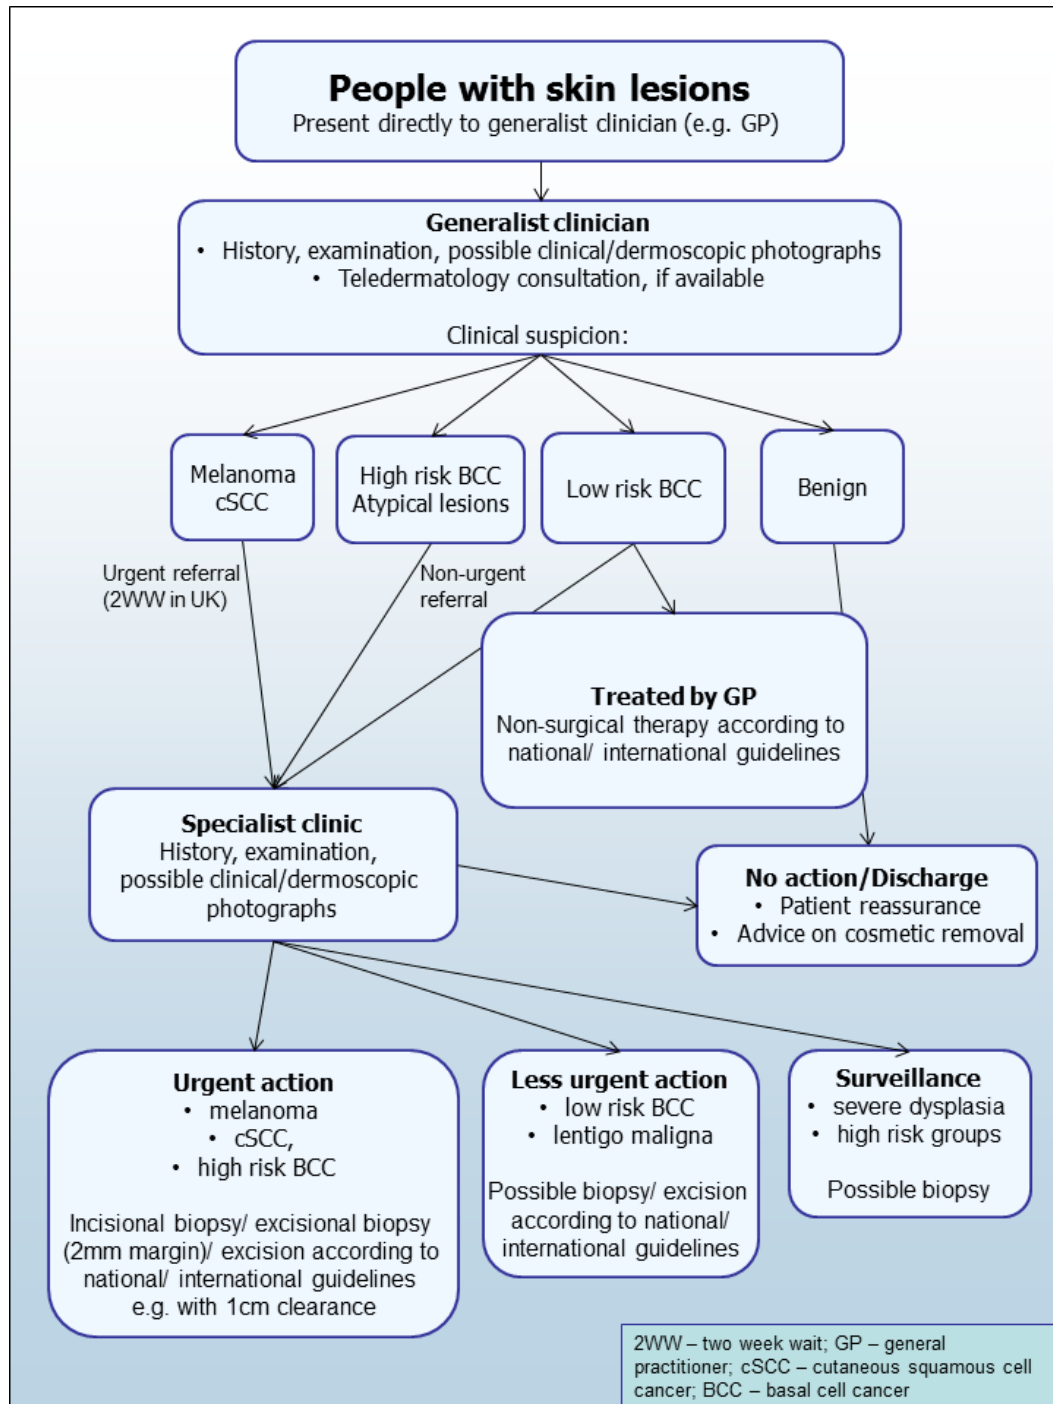

([Chuchu 2018](#)). The store-and-forward approach is advantageous as it requires less sophisticated technology and lower-cost equipment ([Warshaw 2011](#)); however, it does not allow the specialist to take a direct history, request additional views or communicate in detail the purpose of management to the patient or referrer ([Ndegwa 2010](#)).

Live interactive teledermatology uses videoconferencing and image transmission to connect the patient, referrer and dermatologist in real time ([Ndegwa 2010](#)). The dermatologist and patient can interact verbally in a similar manner to a traditional clinic-based encounter, but more extensive telecommunications infrastructure and time are needed ([Ndegwa 2010](#)).

Clinical pathway

The diagnosis of melanoma can take place in primary, secondary and tertiary care settings by both generalist and specialist healthcare providers. In the UK, people with concerns about a new or changing skin lesion will usually present first to their GP or, less commonly, directly to a specialist in secondary care, which could include a dermatologist, plastic surgeon, other specialist surgeon (such as an ear, nose and throat specialist or maxillofacial surgeon), or ophthalmologist ([Figure 2](#)). Current UK guidelines recommend that all suspicious pigmented lesions presenting in primary care should be assessed by taking a clinical history and visual inspection guided by the revised seven-point checklist ([MacKie 1990](#)). Clinicians should refer those with suspected melanoma or cSCC for appropriate specialist assessment within two weeks ([Chao 2014](#); [Marsden 2010](#); [NICE 2015a](#)). Evidence is emerging, however, to suggest that excision of melanoma by GPs is not associated with increased risk compared with outcomes in secondary care ([Murchie 2017](#)). In the UK, low-risk BCC are usually recommended for routine referral, with urgent referral for those in whom a delay could have a significant impact on outcomes, for example due to large lesion size or critical site ([NICE 2015b](#)). Appropriately qualified generalist care providers increasingly undertake management of low-risk BCC in the UK such as by excision of low-risk lesions ([NICE 2010](#)). Similar guidance is in place in Australia ([CCAAC Network 2008](#)).

Figure 2. Current clinical pathway for people with skin lesions.

Teledermatology consultations can aid more appropriate triage of lesions, providing reassurance for benign lesions and referral via urgent or non-urgent routes to secondary care (e.g. for suspected BCC). The distinction between setting and examiner qualifications and experience is important, as specialist clinicians might work in primary care settings (e.g. in the UK, GPs with a special interest in dermatology and skin surgery who have undergone appropriate training), and generalists might practice in secondary care settings (e.g. GPs working alongside dermatologists in secondary care, or plastic surgeons who do not specialise in skin cancer). The level of skill and experience in skin cancer diagnosis varies for both generalist and specialist care providers and impacts on test accuracy. For referred lesions, the specialist clinician will use history-taking, visual inspection of the lesion (in comparison with other lesions on the skin) usually in conjunction with dermoscopic examination, and palpation of the lesion and associated regional nodal basins to inform a clinical decision. If melanoma is suspected, then urgent 2 mm excision biopsy is recommended (Lederman 1985; Lees 1991); for cSCC, predetermined surgical margin excision or a diagnostic biopsy may be considered. BCC and premalignant lesions potentially eligible for non-surgical treatment may undergo a diagnostic biopsy before initiation of therapy. Equivocal melanocytic lesions for which a definitive clinical diagnosis cannot be reached may undergo surveillance to identify any lesion changes that would indicate excision biopsy or reassurance and discharge for lesions that remain stable over a period of time.

Prior test(s)

Although smartphone applications and community- or high street pharmacy-based teledermatology services (e.g. the Boots 'Mole Scanning Service' www.boots.com/health-pharmacy-advice/skin-services/mole-scanning-service) can increasingly be accessed directly by people who have concerns about a skin lesion (Kjome 2017), the diagnosis of skin cancer is still based on history taking and clinical examination by a suitably qualified clinician. In the UK, this is typically undertaken at two decision points - first in primary care where the GP makes a decision to refer or not to refer, and then a second time by a dermatologist or other secondary care clinician where a decision is made to biopsy or excise or not. Visual inspection of the skin is undertaken iteratively, using both implicit pattern recognition (non-analytical reasoning) and more explicit 'rules' based on conscious analytical reasoning (Norman 2009), the balance of which will vary according to experience and familiarity with the diagnostic question. Various attempts have been made to formalise the "mental rules" involved in analytical pattern recognition for melanoma (Friedman 1985; Grob 1998; MacKie 1985; MacKie 1990; Sober 1979; Thomas 1998); however, visual inspection for keratinocyte skin cancers relies primarily on pattern recognition. Accuracy has been shown to vary according to the expertise of the clinician. Primary care physicians have

been reported to miss over 50% of BCCs (Offidani 2002) and to misdiagnose around 33% of BCCs (Gerbert 2000). In contrast, one Australian study found that trained dermatologists were able to detect 98% of BCCs, but with a specificity of only 45% (Green 1988).

A range of technologies have emerged to aid diagnosis to reduce the number of diagnostic biopsies or inappropriate surgical procedures. Dermoscopy using a hand-held microscope has become the most widely used tool used by clinicians to improve diagnostic accuracy of pigmented lesions, in particular for melanoma (Dinnes 2018a); it is less well established for the diagnosis of BCC or cSCC. Dermoscopy (also referred to as dermatoscopy or epiluminescence microscopy) uses a hand-held microscope and incident light (with or without oil immersion) to reveal subsurface images of the skin at increased magnification of $\times 10$ to $\times 100$ (Kittler 2001). Used alongside clinical examination, dermoscopy has been shown in some studies to increase the sensitivity of clinical diagnosis of melanoma from around 60% to as much as 90% (Bono 2006; Carli 2002; Kittler 1999; Stanganelli 2000) with much smaller effects in others (Benelli 1999; Bono 2002). The accuracy of dermoscopy depends on the experience of the examiner (Kittler 2001), with accuracy when used by untrained or less-experienced examiners potentially no better than clinical inspection alone (Binder 1997; Kittler 2002).

The diagnostic accuracy, and comparative accuracy, of visual inspection and dermoscopy have been evaluated in a further three reviews in this series (Dinnes 2018a; Dinnes 2018b; Dinnes 2018c).

Role of index test(s)

The use of teledermatology by primary care or by other generalist clinicians has the potential to ensure that people with suspicious lesions are appropriately referred for examination by a specialist clinician, and people with non-suspicious lesions are appropriately reassured and managed in primary care. If an accurate triage is made, the proportion of people who are referred unnecessarily will be minimised and lesions requiring urgent referral and treatment correctly identified. By creating an environment where there is facilitated access to more specialist services, selective dermatology referral could ultimately reduce costs while enabling a faster, more reliable and more efficient service (Piccolo 2002). Increased information flow between primary care physicians and dermatologists also has the potential effect of increasing knowledge and reducing isolated decision-making (Bashshur 2015).

When diagnosing potentially life-threatening conditions such as melanoma, the consequences of falsely reassuring a person that they do not have skin cancer can be potentially fatal, as the delay to diagnosis means that the window for successful early treatment may be missed. To minimise these false-negative diagnoses, a good

diagnostic test for melanoma demonstrates high sensitivity and high negative predictive value (i.e. very few of those with a negative test result will actually have a melanoma). Giving false-positive test results (meaning the test has poor specificity and a high false-positive rate) resulting in the removal of lesions that are benign, is arguably less of an error than missing a potentially fatal melanoma, but does have implications for patient welfare and costs. False-positive diagnoses cause unnecessary scarring from the biopsy or excision procedure, and increase patient anxiety while they await the definite histology results and increase healthcare costs as the number needed to remove to yield one melanoma diagnosis increases.

Delay in diagnosis of a BCC as a result of a false-negative result is not as serious as for melanoma because BCCs are usually slow growing and unlikely to metastasise. However, delayed diagnosis can result in a larger and more complex excision with consequent greater morbidity. Very sensitive diagnostic tests for BCC may compromise on lower specificity leading to a higher false-positive rate, and an enormous burden of skin surgery, such that a balance between sensitivity and specificity is needed. The situation for cSCC is more similar to melanoma in that the consequences of falsely reassuring a person that they do not have skin cancer can be serious and potentially fatal. Thus, a good diagnostic test for cSCC should demonstrate high sensitivity and a corresponding high negative predictive value. In summary, a test that can reduce false-positive clinical diagnoses without missing true cases of disease has patient and resource benefits. False-positive clinical diagnoses cause unnecessary morbidity from the biopsy, and could lead to initiation of inappropriate therapies and increase patient anxiety.

Alternative test(s)

Teledermatology provides an alternative means for primary care clinicians (and therefore patients) to access specialist opinion compared to the standard referral process from primary to secondary care. Although the general public can also seek advice on skin lesions, they may be concerned about doing so via smartphone applications or from services provided within community or 'high street' pharmacies. These are not considered direct alternatives to teledermatology services.

Several other tests that may have a role in diagnosis of skin cancer have been reviewed as part of our series of systematic reviews, including visual inspection and dermoscopy (Dinnes 2018a; Dinnes 2018b; Dinnes 2018c), smartphone applications (Chuchu 2018), Reflectance confocal microscopy (Dinnes 2018d; Dinnes 2018e), optical coherence tomography (Ferrante di Ruffano 2018a), and computer-assisted diagnosis techniques applied to various types of images including those generated by dermoscopy, diffuse reflectance spectrophotometry and electrical impedance spectroscopy (Ferrante di Ruffano 2018b), and high-frequency ultrasound (Dinnes 2018f). Evidence permitting, the accuracy of

available tests will be compared in an overview review, exploiting within-study comparisons of tests and allowing the analysis and comparison of commonly used diagnostic strategies where tests may be used singly or in combination.

Rationale

Our series of reviews of diagnostic tests used to assist clinical diagnosis of melanoma aimed to identify the most accurate approaches to diagnosis and provide clinical and policy decision-makers with the highest possible standard of evidence on which to base decisions. With increasing rates of skin cancer and the push towards the use of dermoscopy and other high-resolution image analysis in primary care, the anxiety around missing early cases needs to be balanced against the risk of over referrals, to avoid sending too many people with benign lesions for a specialist opinion. It is questionable whether all skin cancers detected by sophisticated techniques, even in specialist settings, help to reduce morbidity and mortality, or whether newer technologies run the risk of increasing false-positive diagnoses. It is also possible that use of some technologies (e.g. widespread use of dermoscopy in primary care with no training), could actually result in harm by missing melanomas if they are used as replacement technologies for traditional history-taking and clinical examination of the entire skin. Many branches of medicine have noted the danger of such "gizmo idolatry" among doctors (Leff 2008).

Although teledermatology is increasingly used, the accuracy of different approaches to providing teledermatology services (e.g. store-and-forward versus live-link modalities, and use of clinical versus dermoscopic images) has yet to be fully established. A review by Warshaw 2011 suggested that both store-and-forward and live-link teledermatology had acceptable diagnostic accuracy and concordance when compared with clinical face-to-face diagnosis; however, clinic-based dermatology had superior diagnostic accuracy (i.e. in comparison to store-and-forward teledermatology consultations). As with any technology requiring significant investment, a full understanding of the benefits including patient acceptability and cost-effectiveness in comparison to usual practice should be obtained before such an approach can be recommended; establishing the accuracy of diagnosis and referral accuracy is one of the key components. Given the rapidly changing evidence base in skin cancer diagnosis, there is a need for an up-to-date analysis of the accuracy of teledermatology for skin cancer diagnosis.

This review followed a generic protocol which covered the full series of Cochrane DTA reviews for the diagnosis of melanoma (Dinnes 2015a); aspects of this review which relate to the diagnosis of BCC and cSCC follow the generic protocol that was written to cover the reviews in the series for the diagnosis of keratinocyte skin cancers (Dinnes 2015b). The 'Background' and 'Methods' sections of this review therefore use some text that was originally published in the protocols (Dinnes 2015a; Dinnes 2015b), and text that overlaps some of our other reviews (Chuchu 2018; Dinnes 2018a; Dinnes 2018b).

OBJECTIVES

To determine the diagnostic accuracy of teledermatology for the detection of any skin cancer (melanoma, BCC or cSCC) in adults, and to compare its accuracy with that of in-person diagnosis.

Accuracy was estimated separately according to the type of teledermatology images used:

- photographic images;
- dermoscopic images;
- photographic and dermoscopic images.

Secondary objectives

- To determine the diagnostic accuracy of teledermatology for the detection of invasive melanoma or atypical intraepidermal melanocytic variants in adults, and to compare its accuracy with that of in-person diagnosis.
- To determine the diagnostic accuracy of teledermatology for the detection of invasive melanoma only, in adults, and to compare its accuracy with that of in-person diagnosis.
- To determine the diagnostic accuracy of teledermatology for the detection of BCC in adults, and to compare its accuracy with that of in-person diagnosis.
- To determine the diagnostic accuracy of teledermatology for the detection of cSCC in adults, and to compare its accuracy with that of in-person diagnosis.
- To determine the referral accuracy of teledermatology (i.e. to compare diagnostic decision making based on teledermatology images with that of an in-person consultation).

Investigation of sources of heterogeneity

We set out to address a range of potential sources of heterogeneity for investigation across our series of reviews, as outlined in our generic protocols ([Dinnes 2015a](#); [Dinnes 2015b](#)), and described in [Appendix 4](#); however, our ability to investigate these was necessarily limited by the available data on each individual test reviewed.

METHODS

Criteria for considering studies for this review

Types of studies

We included test accuracy studies that allow comparison of the result of the index test with that of a reference standard, including the following:

- studies where all participants receive a single index test and a reference standard;
- studies where all participants receive more than one index test(s) and reference standard;
- studies where participants are allocated (by any method) to receive different index tests or combinations of index tests and all receive a reference standard (between-person comparative (BPC) studies);
- studies that recruit series of participants unselected by true disease status;
- diagnostic case-control studies that separately recruit diseased and non-diseased groups (see [Rutjes 2005](#)); however, we did not include studies that compared results for malignant lesions to those for healthy skin (i.e. with no lesion present);
- both prospective and retrospective studies; and
- studies where previously acquired clinical or dermoscopic images were retrieved and prospectively interpreted for study purposes.

We excluded studies from which we could not extract 2×2 contingency data or if they included fewer than five cases of melanoma, BCC or cSCC or fewer than five benign lesions. For studies of referral accuracy where a lesion's final diagnosis was not reported, we required at least five 'positive' cases as identified by the expert diagnosis reference standard. The size threshold of five was arbitrary. However, such small studies are unlikely to add precision to estimate of accuracy.

Studies available only as conference abstracts were excluded; however, attempts were made to identify full papers for potentially relevant conference abstracts ([Searching other resources](#)).

Participants

We included studies in adults with lesions suspicious for skin cancer or adults at high risk of developing skin cancer. We excluded studies that recruited only participants with malignant or benign final diagnoses.

We excluded studies conducted in children, or which clearly reported inclusion of more than 50% of participants aged 16 and under.

Index tests

We included studies evaluating teledermatology alone, or teledermatology in comparison with face-to-face diagnosis. The following index tests were eligible for inclusion:

- store-and-forward teledermatology;
- real-time 'live link' teledermatology.

Data for face-to-face clinical diagnosis against a histological reference standard was also included where reported, to allow a direct comparison with teledermatology to be made.

Although primary care clinicians can in practice be specialists in skin cancer, we considered primary care physicians as generalist practitioners and dermatologists as specialists. Within each group, we extracted any reporting of special interest or accreditation in skin cancer.

Target conditions

We defined the primary target condition as the detection of any skin cancer, primarily cutaneous melanoma, BCC or cSCC.

We considered four additional definitions of the target condition in secondary analyses, namely, the detection of:

- invasive cutaneous melanoma alone;
- invasive cutaneous melanoma or atypical intraepidermal melanocytic variants (including melanoma in situ, lentigo maligna);
- BCC;
- cSCC.

We also considered referral accuracy, comparing decision making from teledermatology compared with the face-to-face decisions for the same lesions. These decisions could have included the decision to excise a lesion, follow-up a lesion or refer a lesion for face-to-face assessment.

Reference standards

Teledermatology can be assessed in terms of diagnostic accuracy in comparison to the final lesion diagnosis and referral accuracy in comparison to a face-to-face expert management decision.

To establish diagnostic accuracy, the ideal reference standard was histopathological diagnosis in all eligible lesions. A qualified pathologist or dermatopathologist should have performed histopathology. Ideally, reporting should have been standardised detailing a minimum dataset to include the histopathological features of melanoma to determine the AJCC Staging System (e.g. Slater 2014). We did not apply this minimum dataset requirement as a necessary inclusion criterion, but extracted any pertinent information.

Partial verification (applying the reference test only to a subset of those undergoing the index test) was of concern given that lesion excision or biopsy were unlikely to be carried out for all benign-appearing lesions within a representative population sample. Therefore, to reflect what happens in reality, we accepted clinical follow-up of benign-appearing lesions as an eligible reference standard, while recognising the risk of differential verification bias (as misclassification rates of histopathology and follow-up will differ). Additional eligible reference standards included cancer registry follow-up and 'expert opinion' with no histology or clinical follow-up.

All of the above were considered eligible reference standards for establishing lesion final diagnoses (diagnostic accuracy) with the following caveats:

- all study participants with a final diagnosis of the target disorder must have had a histological diagnosis, either subsequent to the application of the index test or after a period of clinical follow-up, and
- at least 50% of all participants with benign lesions must have had either a histological diagnosis or clinical follow-up to confirm benignity.

To establish referral accuracy of teledermatology (i.e. the ability of the remote observer to approximate an in-person diagnosis), the action recommended by the remote observer was compared with an in-person 'expert opinion' reference standard (i.e. the diagnosis or management recommendation of an appropriately qualified clinician made face-to-face with the study participant).

Search methods for identification of studies

Electronic searches

The Information Specialist (SB) carried out a comprehensive search for published and unpublished studies. A single large literature search was conducted to cover all topics in the programme grant (see Appendix 1 for a summary of reviews included in the programme grant). This allowed for the screening of search results for potentially relevant papers for all reviews at the same time. A search combining disease related terms with terms related to the test names, using both text words and subject headings was formulated. The search strategy was designed to capture studies evaluating tests for the diagnosis or staging of skin cancer. As the majority of records were related to the searches for tests for staging of disease, a filter using terms related to cancer staging and to accuracy indices was applied to the staging test search, to try to eliminate irrelevant studies, for example, those using imaging tests to assess treatment effectiveness. A sample of 300 records that would be missed by applying this filter was screened and the filter adjusted to include potentially relevant studies. When piloted on MEDLINE, inclusion of the filter for the staging tests reduced the overall numbers by around 6000. The final search strategy, incorporating the filter, was subsequently applied to all bibliographic databases as listed below (Appendix 5). The final search result was cross-checked against the list of studies included in five systematic reviews; our search identified all but one of the studies, and this study was not indexed on MEDLINE. The Information Specialist devised the search strategy, with input from the Information Specialist from Cochrane Skin. No additional limits were used. We searched the following bibliographic databases to 29 August 2016 for relevant published studies:

- MEDLINE via Ovid (from 1946);

- MEDLINE In-Process & Other Non-Indexed Citations via Ovid;
- Embase via Ovid (from 1980).

We searched the following bibliographic databases to 30 August 2016 for relevant published studies:

- the Cochrane Central Register of Controlled Trials (CENTRAL) 2016, Issue 7, in the Cochrane Library;
- the Cochrane Database of Systematic Reviews (CDSR) 2016, Issue 8, in the Cochrane Library;
- Cochrane Database of Abstracts of Reviews of Effects (DARE) 2015, Issue 2;
- CRD HTA (Health Technology Assessment) database 2016, Issue 3; and
- CINAHL (Cumulative Index to Nursing and Allied Health Literature via EBSCO from 1960).

We searched the following databases for relevant unpublished studies using a strategy based on the MEDLINE search:

- CPCI (Conference Proceedings Citation Index), via Web of Science™ (from 1990; searched 28 August 2016); and
- SCI Science Citation Index Expanded™ via Web of Science™ (from 1900, using the 'Proceedings and Meetings Abstracts' Limit function; searched 29 August 2016).

We searched the following trials registers using the search terms 'melanoma', 'squamous cell', 'basal cell' and 'skin cancer' combined with 'diagnosis':

- Zetoc (from 1993; searched 28 August 2016).
- The US National Institutes of Health Ongoing Trials Register (www.clinicaltrials.gov); searched 29 August 2016.
- NIHR Clinical Research Network Portfolio Database (www.nihr.ac.uk/research-and-impact/nihr-clinical-research-network-portfolio/); searched 29 August 2016.
- The World Health Organization International Clinical Trials Registry Platform (apps.who.int/trialsearch/); searched 29 August 2016.

We aimed to identify all relevant studies regardless of language or publication status (published, unpublished, in press, or in progress). We applied no date limits.

Searching other resources

We screened relevant systematic reviews identified by the searches for their included primary studies, and included any missed by our searches. We checked the reference lists of all included papers, and subject experts within the author team reviewed the final list of included studies. There was no electronic citation searching.

Data collection and analysis

Selection of studies

At least one review author (JDi or NC) screened titles and abstracts, and discussed and resolved any queries by consensus. A pilot screen of 539 MEDLINE references showed good agreement (89% with a kappa of 0.77) between screeners. Primary test accuracy studies and test accuracy reviews (for scanning of reference lists) of any test used to investigate suspected melanoma, BCC or cSCC were included at initial screening. Both a clinical reviewer (from one of a team of 12 clinician reviewers) and a methodologist reviewer (JDi or NC) independently applied inclusion criteria to all full-text articles ([Appendix 6](#)), and resolved disagreements by consensus or by a third party (JDe, CD, HW and RM). We contacted authors of eligible studies when insufficient data were presented to allow for the construction of 2×2 contingency tables.

Data extraction and management

One clinical (as detailed above) and one methodological reviewer (JDi, NC or LFR) independently extracted data concerning details of the study design, participants, index test(s) or test combinations, and criteria for index test positivity, reference standards and data required to complete a 2×2 diagnostic contingency table for each index test using a piloted data extraction form. Data were extracted at all available index test thresholds. We resolved disagreements by consensus or by a third party (JDe, CD, HW, and RM). We entered data into Review Manager 5 ([Review Manager 2014](#)).

We contacted authors of included studies where information related to the target condition (in particular to allow the differentiation of invasive cancers from 'in situ' variants) or there were missing diagnostic threshold. We contacted authors of conference abstracts published from 2013 to 2015 to ask whether full data were available. If there was no full paper, we marked conference abstracts as 'pending' and will revisit them in a future review update.

Dealing with multiple publications and companion papers

Where we identified multiple reports of a primary study, we maximised yield of information by collating all available data. Where there were inconsistencies in reporting or overlapping study populations, we contacted study authors for clarification in the first instance. If this contact with authors was unsuccessful, we used the most complete and up-to-date data source where possible.

Assessment of methodological quality

We assessed risk of bias and applicability of included studies using the QUADAS-2 checklist ([Whiting 2011](#)), tailored to the review topic (see [Appendix 7](#)). We piloted the modified QUADAS-2 tool on five included full-text articles. One clinical reviewer (as detailed above) and one methodological reviewer (JDi, NC or LFR) independently assessed quality for the remaining studies; we

resolved disagreements by consensus or by a third party (JDe, CD, HW and RM).

Statistical analysis and data synthesis

Our unit of analysis was the lesion rather than the participant. This is because firstly, in skin cancer initial treatment is directed to the lesion rather than systemically (thus it is important to be able to correctly identify cancerous lesions for each person), and secondly, it is the most common way in which the primary studies reported data. Although there is a theoretical possibility of correlations of test errors when the same people contribute data for multiple lesions, most studies included very few people with multiple lesions and any potential impact on findings was likely to be very small, particularly in comparison with other concerns regarding risk of bias and applicability. For each analysis, we included only one dataset per study to avoid multiple counting of lesions.

For the diagnosis of melanoma, any BCCs or invasive cSCCs that were correctly identified by teledermatology but that were identified as melanomas in the 'disease-negative' group were considered as true-negative test results rather than as false positives, on the basis that excision of such lesions would be a positive outcome for the participants concerned. However, for the diagnosis of BCC, we considered any melanomas or cSCCs that were mistaken for BCCs as false-positive results. This decision was taken on the basis that the clinical management of a lesion considered to be a BCC might be quite different to that for a melanoma or cSCC and could potentially lead to a negative outcome for the participants concerned, for example if a treatment other than excision was initiated.

For preliminary investigations of the data, we plotted estimates of sensitivity and specificity on coupled forest plots and in receiver operating characteristic (ROC) space for each index test, target condition and reference standard combination. When meta-analysis was possible and there were at least four studies, we used a bivariate model to obtain summary estimates of sensitivity and specificity (Chu 2006; Reitsma 2005). When there were fewer than four studies and little or no heterogeneity in ROC space, we pooled sensitivity and specificity using fixed-effect logistic regression (Takwoingi 2017). We included data for face-to-face diagnosis only if reported in comparison to teledermatology diagnosis. Using these direct (head-to-head) comparisons, a comparative meta-analysis to compare the accuracy of teledermatology with face-to-face diagnosis was not possible because there were too few

studies. However, we tabulated results from the studies and estimated differences in sensitivity and specificity. Since these comparative studies did not report the cross-classified results of the two index tests in participants with and without a particular form of skin cancer, we were unable to compute CIs for the differences using methods that accounted for the paired nature of the data. Therefore, we assumed independence between the sensitivities and between the specificities of the two tests, and calculated 95% CIs for the differences using the Newcombe-Wilson method without continuity correction (Newcombe 1998). We performed analyses using Stata version 15 (Stata 2017).

Investigations of heterogeneity

We examined heterogeneity by visually inspecting forest plots of sensitivity and specificity, and summary ROC (SROC) plots. We were unable to perform meta-regression to investigate potential sources of heterogeneity due to insufficient numbers of studies.

Sensitivity analyses

There were too few data to perform sensitivity analyses.

Assessment of reporting bias

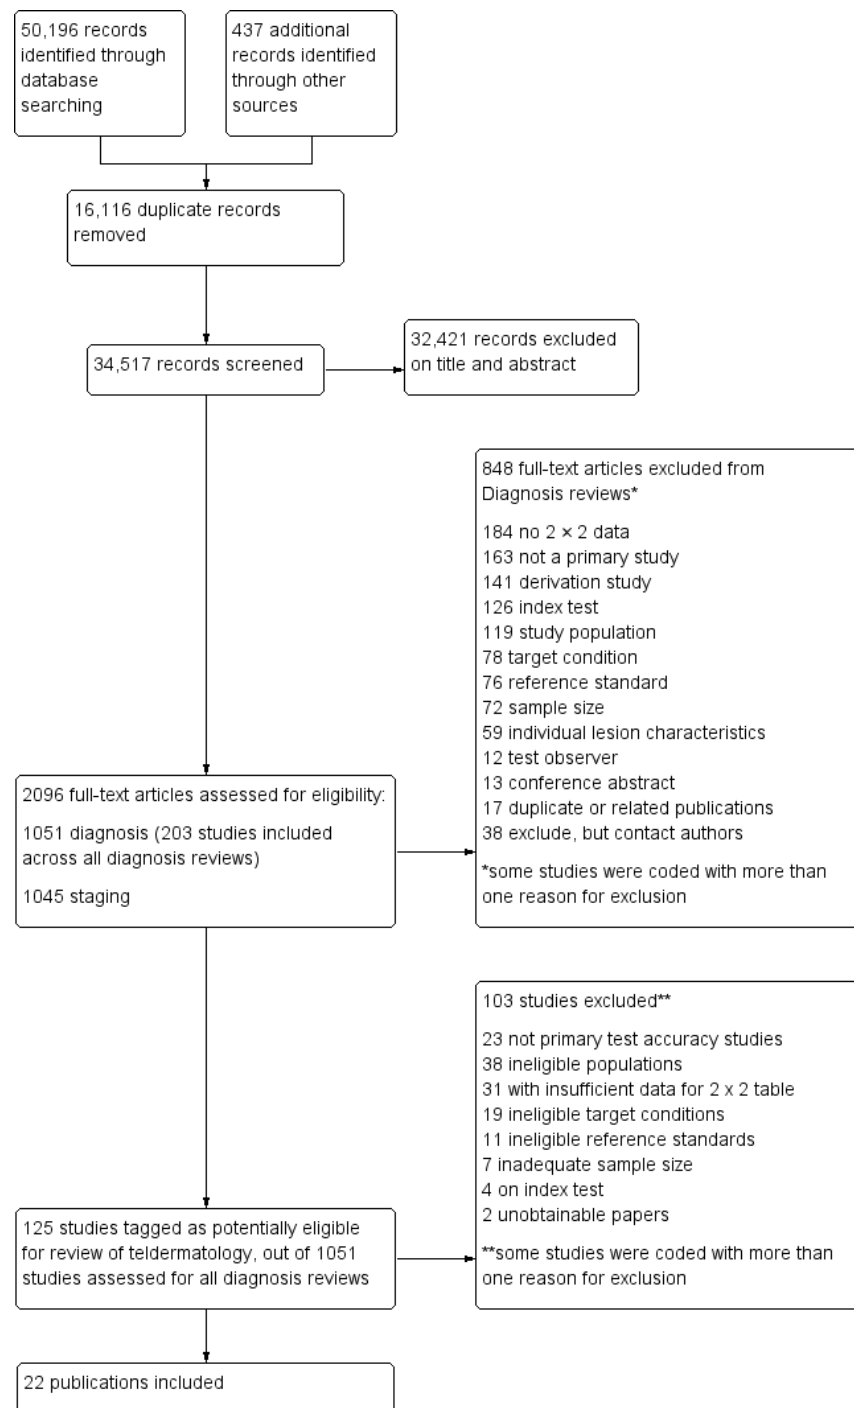

Because of uncertainty about the determinants of publication bias for diagnostic accuracy studies and the inadequacy of tests for detecting funnel plot asymmetry (Deeks 2005), we did not perform tests to detect publication bias.

RESULTS

Results of the search

The search identified 34,517 unique references and screened them for inclusion after reading the title and abstract. Of these, we reviewed 1051 full-text papers for eligibility for any one of the suite of reviews of tests to assist in the diagnosis of melanoma or keratinocyte skin cancer; 203 publications were included in at least one review in our series and 848 publications were excluded (see Figure 3; PRISMA flow diagram of search and eligibility results).

Figure 3. PRISMA flow diagram.

Of the 125 studies tagged as potentially eligible for this review of teledermatology, we included 22 publications. Exclusions from the review were primarily due to: lack of test accuracy data to complete a 2x2 contingency table (31 studies), ineligible populations (38 studies) or target conditions (19 studies), not accuracy studies (23 studies) and inadequate sample size (fewer than five cases of skin cancer, fewer than five benign lesions, or for referral accuracy, fewer than five 'positive' cases identified by the expert diagnosis reference standard) (seven studies) or reference standards (11 studies). Of the 31 studies for which a 2x2 table could not be constructed, 11 reported only agreement between observers or between teledermatology and the reference standard and 14 had at least one piece of missing data. A list of the 103 studies with reasons for exclusion is provided in the [Characteristics of excluded studies](#) table, with a list of all studies excluded from the full series of reviews available as a separate pdf (please contact skin.cochrane.org for a copy of the pdf).

We contacted the corresponding authors of 12 studies and asked them to supply further information to allow study inclusion or to clarify diagnostic thresholds or target condition definition. We received responses from four authors allowing inclusion of all four studies in this review ([Borve 2015](#); [Mahendran 2005](#); [Warshaw 2010b](#); [Wolf 2013](#)). One of the four authors was unable to provide all of the information requested such that the data presented in the paper could only be partially included in this review ([Warshaw 2010b](#)).

The 22 included study publications reported on 22 cohorts of lesions and provided 96 datasets (individual 2x2 contingency tables). Sixteen studies (73%) including 4057 lesions and 879 malignant cases reported data for the *diagnostic* accuracy of teledermatology ([Arzberger 2016](#); [Borve 2015](#); [Bowns 2006](#); [Congalton 2015](#); [Coras 2003](#); [Ferrara 2004](#); [Grimaldi 2009](#); [Jolliffe 2001a](#); [Kroemer 2011](#); [Massone 2014](#); [Moreno Ramirez 2005](#); [Piccolo 2000](#); [Piccolo 2004](#); [Silveira 2014](#); [Warshaw 2010b](#); [Wolf 2013](#)), five of which also reported data for the diagnostic accuracy of expert face-to-face clinical diagnosis ([Coras 2003](#); [Jolliffe 2001a](#); [Kroemer 2011](#); [Piccolo 2000](#); [Warshaw 2010b](#)). Six studies (27%) including 1449 lesions reported data for the *referral* accuracy of teledermatology (i.e. teledermatology diagnosis or management action as the index test versus expert face-to-face diagnosis or management action as the reference standard) ([Jolliffe 2001b](#); [Mahendran 2005](#); [Manahan 2015](#); [Oliveira 2002](#); [Phillips 1998](#); [Shapiro 2004](#)); these studies included 270 'positive' cases as determined by the reference standard face-to-face decision. A cross-tabulation of studies by reported comparisons, target conditions and types of image used is provided in [Table 1](#) and summary study details is presented in [Appendix 8](#).

Studies were primarily prospective case series (18 studies; 82%), with two retrospective case series (9%) ([Moreno Ramirez 2005](#); [Piccolo 2004](#)), and two case-control studies (9%) ([Ferrara 2004](#);

[Wolf 2013](#)), three of which retrospectively selected previously acquired images for prospective evaluation in the study ([Ferrara 2004](#); [Piccolo 2004](#); [Wolf 2013](#)). Studies were conducted in: Europe (14 (64%) studies), including five studies from Austria ([Arzberger 2016](#); [Kroemer 2011](#); [Massone 2014](#); [Piccolo 2000](#); [Piccolo 2004](#)), and four from the UK ([Bowns 2006](#); [Jolliffe 2001a](#); [Jolliffe 2001b](#); [Mahendran 2005](#)); North America (four (18%) studies; [Phillips 1998](#); [Shapiro 2004](#); [Warshaw 2010b](#); [Wolf 2013](#)); or South America (two studies; 9%; [Oliveira 2002](#); [Shapiro 2004](#)); or in Australia ([Manahan 2015](#)); or New Zealand ([Congalton 2015](#)) (9%). Eight (36.4%) studies included only pigmented ([Coras 2003](#); [Grimaldi 2009](#); [Jolliffe 2001a](#); [Moreno Ramirez 2005](#); [Piccolo 2000](#); [Wolf 2013](#)) or melanocytic ([Ferrara 2004](#); [Piccolo 2004](#)) lesions ([Piccolo 2004](#) restricting to acral lesions only); the remainder included any suspicious lesion.

Ten studies were based in primary care or community-based settings. Seven studies acquired lesion images in primary care ([Borve 2015](#); [Grimaldi 2009](#); [Mahendran 2005](#); [Massone 2014](#); [Moreno Ramirez 2005](#); [Oliveira 2002](#); [Shapiro 2004](#)), two studies were in a community skin cancer screening outreach programme with image acquisition for 'remote' assessment by specialists in a secondary care setting ([Silveira 2014](#)) or using live transmission video-conferencing ([Phillips 1998](#)), and one study recruited participants at high risk of melanoma who took images of their own lesions that they 'did not like the look of' using a smartphone ([Manahan 2015](#)). There were no studies conducted in high street pharmacy-type settings. Five of the 10 studies reported the diagnostic accuracy of the teledermatology image-based assessment ([Borve 2015](#); [Grimaldi 2009](#); [Massone 2014](#); [Moreno Ramirez 2005](#); [Silveira 2014](#)), and five examined referral accuracy, comparing the teledermatology assessment against specialist in-person assessment ([Mahendran 2005](#); [Manahan 2015](#); [Oliveira 2002](#); [Phillips 1998](#); [Shapiro 2004](#)). Of these studies, nine were prospective in design and one was retrospective ([Moreno Ramirez 2005](#)).

Twelve studies acquired lesion images at a secondary care dermatology or pigmented lesion clinic ([Arzberger 2016](#); [Congalton 2015](#); [Ferrara 2004](#); [Jolliffe 2001a](#); [Jolliffe 2001b](#); [Kroemer 2011](#); [Piccolo 2000](#); [Piccolo 2004](#); [Warshaw 2010b](#); [Wolf 2013](#)), from a private dermatology practice ([Coras 2003](#)), or in a medical imaging unit ([Bowns 2006](#)), at the time of the patient consultation, and a second dermatologist made remote image-based diagnoses. Of these studies, nine were prospective in design, two studies retrieved routinely collected lesion images for prospective 'teledermatology' examination ([Piccolo 2004](#); [Wolf 2013](#)), and one did not clearly report how lesion images were acquired ([Ferrara 2004](#)). Six studies reported data only for the diagnostic accuracy of specialist image-based assessment ([Arzberger 2016](#); [Bowns 2006](#); [Congalton 2015](#); [Ferrara 2004](#); [Piccolo 2004](#); [Wolf 2013](#)), five compared the diagnostic accuracy of image-based diagnosis to that of a dermatolo-

gist's face-to-face diagnosis (Coras 2003; Jolliffe 2001a; Kroemer 2011; Piccolo 2000; Warshaw 2010b), and one examined referral accuracy, comparing specialist image-based assessment against specialist in-person assessment (Jolliffe 2001b).

Ten evaluations reported data using photographic images for teledermatology consultations (Jolliffe 2001a; Jolliffe 2001b; Kroemer 2011; Mahendran 2005; Moreno Ramirez 2005; Oliveira 2002; Shapiro 2004; Silveira 2014; Warshaw 2010b; Wolf 2013), nine for a combination of clinical and dermoscopic images (Arzberger 2016; Borve 2015; Bowns 2006; Congalton 2015; Coras 2003; Grimaldi 2009; Manahan 2015; Massone 2014; Piccolo 2000), and three reported data for diagnosis using dermoscopic images only (Ferrara 2004; Kroemer 2011; Piccolo 2004). The final study reported referral accuracy data for live-link teledermatology using three cameras: a full-body camera, a lens for close-up views and a magnifying lens to allow magnified examination and examination with polarised light (Phillips 1998). The Warshaw 2010b paper also reported accuracy data for diagnosis using a combination of photographic and dermoscopic images; however, we were unable to obtain underlying 2×2 data to allow the inclusion of this aspect of the study.

Images for store and forward teledermatology were obtained using a mobile phone camera alone (Kroemer 2011) or coupled with a dermatoscope (Borve 2015; Kroemer 2011; Manahan 2015); using still images from a video camera (Jolliffe 2001a; Jolliffe 2001b); using a combination of film and digital images (Ferrara 2004); or using a digital camera (13 studies) to acquire photographs (Mahendran 2005; Moreno Ramirez 2005; Oliveira 2002; Shapiro 2004; Silveira 2014; Warshaw 2010b; Wolf 2013), dermoscopic images (Ferrara 2004; Piccolo 2004), or both (Arzberger 2016; Congalton 2015; Coras 2003; Grimaldi 2009; Massone 2014; Piccolo 2000). Bowns 2006 acquired photographic and dermoscopic images in a medical photography unit (equipment not described). See the [Characteristics of included studies](#) table for details of the digital cameras and mobile phones used. Eighteen (82%) studies provided observers with additional clinical information along with the digital image of the lesion, three did not clearly report whether additional clinical information was provided (Arzberger 2016; Grimaldi 2009; Manahan 2015), and one did not provide any further participant-related information (Wolf 2013). The remote observers were dermatologists in 19 (86%) studies, oncologists in one, and a mixture of dermatologists and other healthcare professionals (e.g. oncologists, plastic surgeons) in two (9%).

The five studies providing a direct comparison of teledermatology with in-person evaluation by a dermatologist based diagnosis on visual inspection of the lesion with dermoscopy used for some (proportions not reported) (Coras 2003; Jolliffe 2001a; Kroemer 2011; Warshaw 2010b), or for all lesions (Piccolo 2000). One study reported using pattern analysis (Coras 2003), and the remaining three (50%) studies did not specify any algorithm used to aid diagnosis. The direct comparison of teledermatology with

in-person evaluation by a GP provided in Grimaldi 2009 was not included in this review as it is not directly relevant to teledermatology in this context.

For the 16 studies reporting diagnostic accuracy, 11 (69%) used histology alone as the reference standard (Arzberger 2016; Congalton 2015; Coras 2003; Ferrara 2004; Jolliffe 2001a; Kroemer 2011; Piccolo 2000; Piccolo 2004; Silveira 2014; Warshaw 2010b; Wolf 2013), three (19%) used both histology and expert opinion for some benign lesions (Borve 2015; Bowns 2006; Massone 2014), and two (12%) used histology and follow-up of clinically benign-appearing lesions (Grimaldi 2009; Moreno Ramirez 2005). The median number of study participants was 77 (interquartile range (IQR) 4p to 182) (reported in 10 studies), and median number of lesions was 116 (IQR 45 to 240). The median prevalence of skin cancer was 30% (IQR 21% to 45%) and median percentage of men was 46% (IQR 35% to 47%) (reported in nine studies). Where reported (eight studies), the median age was 52 years (IQR 43 to 65) (reported in eight studies). Four of the 16 diagnostic accuracy studies did not report the range in age of included participants (Bowns 2006; Coras 2003; Grimaldi 2009; Wolf 2013), four restricted inclusion to adults only (Borve 2015; Massone 2014; Silveira 2014; Warshaw 2010b), and eight included participants under the age of 16 years (Arzberger 2016; Congalton 2015; Ferrara 2004; Jolliffe 2001a; Kroemer 2011; Moreno Ramirez 2005; Piccolo 2002; Piccolo 2004); however, data were not presented to allow data to be extracted excluding children.

For the six studies reporting referral accuracy, the same dermatologist undertaking the teledermatology assessment made the face-to-face reference standard diagnosis, either within one to two weeks (Mahendran 2005; Oliveira 2002), or with a gap of several months between assessments (Jolliffe 2001b), by a dermatology trainee under the supervision of the teledermatologist (Manahan 2015), or a different dermatologist (Phillips 1998; Shapiro 2004). The median number of study participants was 50 (IQR 49 to 72) (reported in all six studies), and median number of lesions was 107 (IQR 94 to 253). The reported decisions of the face-to-face expert included diagnosis of malignancy (Oliveira 2002; Phillips 1998), decision to excise (Mahendran 2005; Phillips 1998; Shapiro 2004), or decision to see face-to-face (Jolliffe 2001b; Manahan 2015); the median overall percentage of 'positive' expert diagnoses was 15% (IQR 10% to 41%). One study reported the median age of included participants was 46.7 years (Phillips 1998); two studies reported age ranges of 8 to 94 years (Jolliffe 2001b), and 50 to 64 years (Manahan 2015); and four did not report the range in ages (Mahendran 2005; Oliveira 2002; Phillips 1998; Shapiro 2004). The percentage of men ranged from 15.7% (Phillips 1998) to 49% (Manahan 2015) (reported in three studies).

Methodological quality of included studies

The overall methodological quality of included studies is summarised in Figure 4 and Figure 5. At least half of studies were

at high or unclear risk of bias for participant selection, reference standard, and flow and timing domains, while the majority were at low risk for the index test. The applicability of study findings were of high or unclear concern for the majority of studies in all domains assessed.

Figure 4. Risk of bias and applicability concerns graph: review authors' judgements about each domain presented as percentages across included studies.

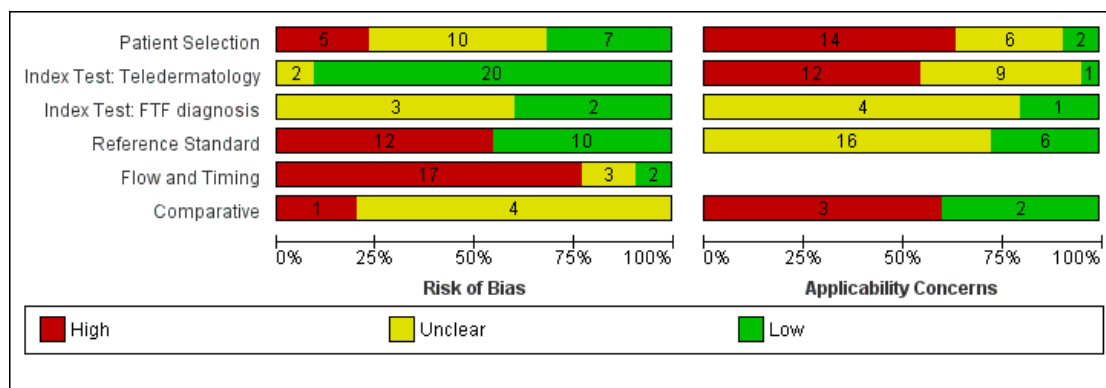

Figure 5. Risk of bias and applicability concerns summary: review authors' judgements about each domain for each included study.

	Risk of Bias						Applicability Concerns

High
 Unclear
 Low

For participant selection, seven (32%) studies were at low risk of bias (Borve 2015; Bowns 2006; Grimaldi 2009; Jolliffe 2001b; Mahendran 2005; Oliveira 2002; Warshaw 2010b), and five (23%) studies were at high risk (Congalton 2015; Ferrara 2004; Massone 2014; Moreno Ramirez 2005; Wolf 2013). Four studies applied inappropriate participant exclusions (such as excluding poor-quality images, or difficult to diagnose lesions) (Congalton 2015; Massone 2014; Moreno Ramirez 2005; Wolf 2013); and two studies used a case-control type study design with separate selection of malignant cases and lesions with benign diagnosis (Ferrara 2004; Wolf 2013). Fourteen studies were at high concern for applicability of participants due to recruitment from secondary care or specialist clinics rather than from the primary setting in which teledermatology is more likely to be used (12/22; Arzberger 2016; Bowns 2006; Congalton 2015; Coras 2003; Jolliffe 2001a; Jolliffe 2001b; Kroemer 2011; Moreno Ramirez 2005; Piccolo 2000; Piccolo 2004; Warshaw 2010b; Wolf 2013), and/or due to inclusion of multiple lesions per participant (6/22; Congalton 2015; Grimaldi 2009; Jolliffe 2001b; Kroemer 2011; Manahan 2015; Warshaw 2010b). Two studies were at low concern for participant applicability (Oliveira 2002; Phillips 1998).

For the index test, all of the teledermatology assessments were at low risk of bias for the index test apart from Phillips 1998, in which it was unclear whether the teledermatology diagnoses were made blinded to the decision to the face-to-face clinician (reference standard). One study was judged of low concern for applicability of teledermatology (Massone 2014), and 12 (45%) studies were of high concern (Arzberger 2016; Bowns 2006; Congalton 2015; Coras 2003; Ferrara 2004; Jolliffe 2001a; Jolliffe 2001b; Kroemer 2011; Piccolo 2000; Piccolo 2004; Warshaw 2010b; Wolf 2013), due to images acquired by dermatologists based in secondary care settings or from pigmented lesion clinic databases rather than images acquired in primary care. For the five studies reporting direct comparisons of teledermatology with face-to-face expert clinical diagnoses, two (40%) were at low risk of bias (Coras 2003; Warshaw 2010b) and three (60%) were judged unclear, as the thresholds used were not clearly prespecified (Jolliffe 2001a; Kroemer 2011; Piccolo 2000). For the comparison between tests, there was no blinding between store-and-forward teledermatology and face-to-face clinical diagnosis in Jolliffe 2001a; the remaining four comparative studies did not describe any blinding (Coras 2003; Kroemer 2011; Piccolo 2000; Warshaw 2010b). One (20%) study was of low concern for applicability of the face-to-face diagnosis (Coras 2003), and four of unclear concern of applicability as the thresholds used for diagnosis were not clearly reported to allow replication of methods (Jolliffe 2001a; Kroemer 2011; Piccolo 2000; Warshaw 2010b).

For the reference standard domain, 10 (45%) studies were at low risk of bias (Arzberger 2016; Congalton 2015; Coras 2003; Ferrara 2004; Jolliffe 2001a; Piccolo 2000; Piccolo 2004; Silveira 2014;

Warshaw 2010b; Wolf 2013), and 12 (55%) were at high risk either because they were referral accuracy studies using only expert face-to-face diagnosis as the reference standard (Jolliffe 2001b; Mahendran 2005; Manahan 2015; Oliveira 2002; Phillips 1998; Shapiro 2004), or because they were diagnostic accuracy studies that did not meet our criteria for an adequate reference standard (i.e. greater than 80% of lesions with histology and up to 20% with clinical follow-up; see Appendix 7) (Borve 2015; Bowns 2006; Grimaldi 2009; Kroemer 2011; Massone 2014; Moreno Ramirez 2005). Only two studies clearly reported blinding of the reference standard diagnosis to the teledermatology assessment (Phillips 1998; Shapiro 2004), and two did not implement any blinding (Mahendran 2005; Oliveira 2002); these were all referral accuracy studies. Six studies were of low concern for the applicability of the reference standard, including three of the 16 diagnostic accuracy studies that clearly reported the level of experience of the histopathologist (Ferrara 2004; Piccolo 2004; Warshaw 2010b), and three of the six referral accuracy studies that reported the expertise of the face-to-face reference standard diagnosis (Jolliffe 2001b; Mahendran 2005; Shapiro 2004).

For flow and timing of participants, two referral accuracy studies were at low risk of bias (Jolliffe 2001b; Phillips 1998), and 17 (77%) were at high risk of bias; either because they did not use the same reference standard for all participants (Borve 2015; Bowns 2006; Grimaldi 2009; Massone 2014; Moreno Ramirez 2005), or they did not include all study participants in the final analysis (Arzberger 2016; Congalton 2015; Coras 2003; Jolliffe 2001a; Kroemer 2011; Mahendran 2005; Manahan 2015; Massone 2014; Moreno Ramirez 2005; Oliveira 2002; Shapiro 2004; Silveira 2014; Warshaw 2010b; Wolf 2013). Fourteen (64%) studies did not clearly report the interval between reference standard and index test (Arzberger 2016; Congalton 2015; Coras 2003; Ferrara 2004; Grimaldi 2009; Jolliffe 2001a; Kroemer 2011; Manahan 2015; Massone 2014; Moreno Ramirez 2005; Piccolo 2000; Piccolo 2004; Warshaw 2010b; Wolf 2013).

Findings

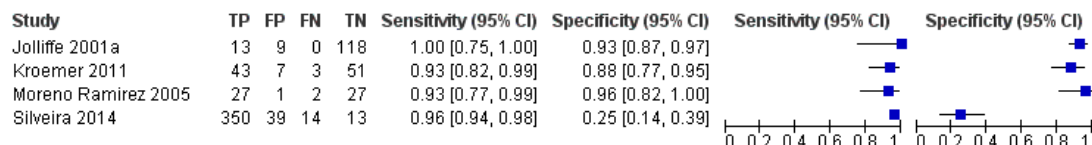

Study results are summarised below according to target condition with results of meta-analyses in Table 2 with summary details in Appendix 8. Lack of data and between-study variation in populations, approaches to teledermatology and target conditions considered, limited the pooled analyses that could be undertaken.

1. Target condition: detection of any skin cancer

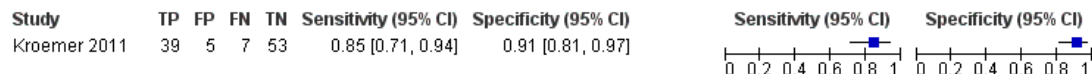

Seven studies with 1588 lesions and 638 cases of skin cancer reported the diagnostic accuracy of teledermatology assessment for the detection of the primary target condition of any skin cancer. Forest plots of study data are provided in Figure 6 with results of meta-analysis in Figure 7.

Figure 6. Forest plot of tests for the detection of any skin cancer (any). CI: confidence interval; FN: false negative; FP: false positive; TN: true negative; TP: true positive.

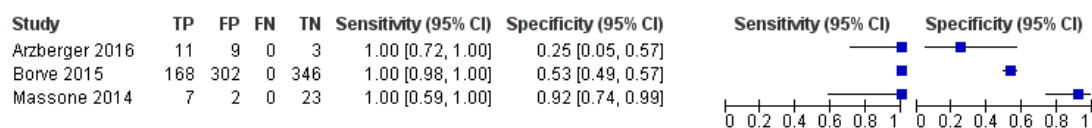

Teledermatology – photographic image vs histology (any)

Teledermatology – dermoscopic image vs histology (any)

Teledermatology – photographic + dermoscopic image vs histology (any)

Expert face-to-face (visual inspection (VI) + dermoscopy) vs histology (any)

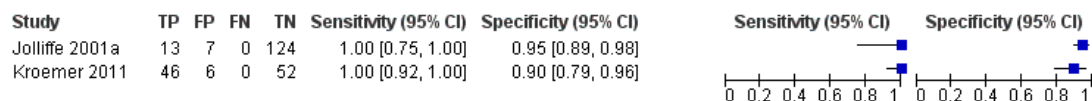

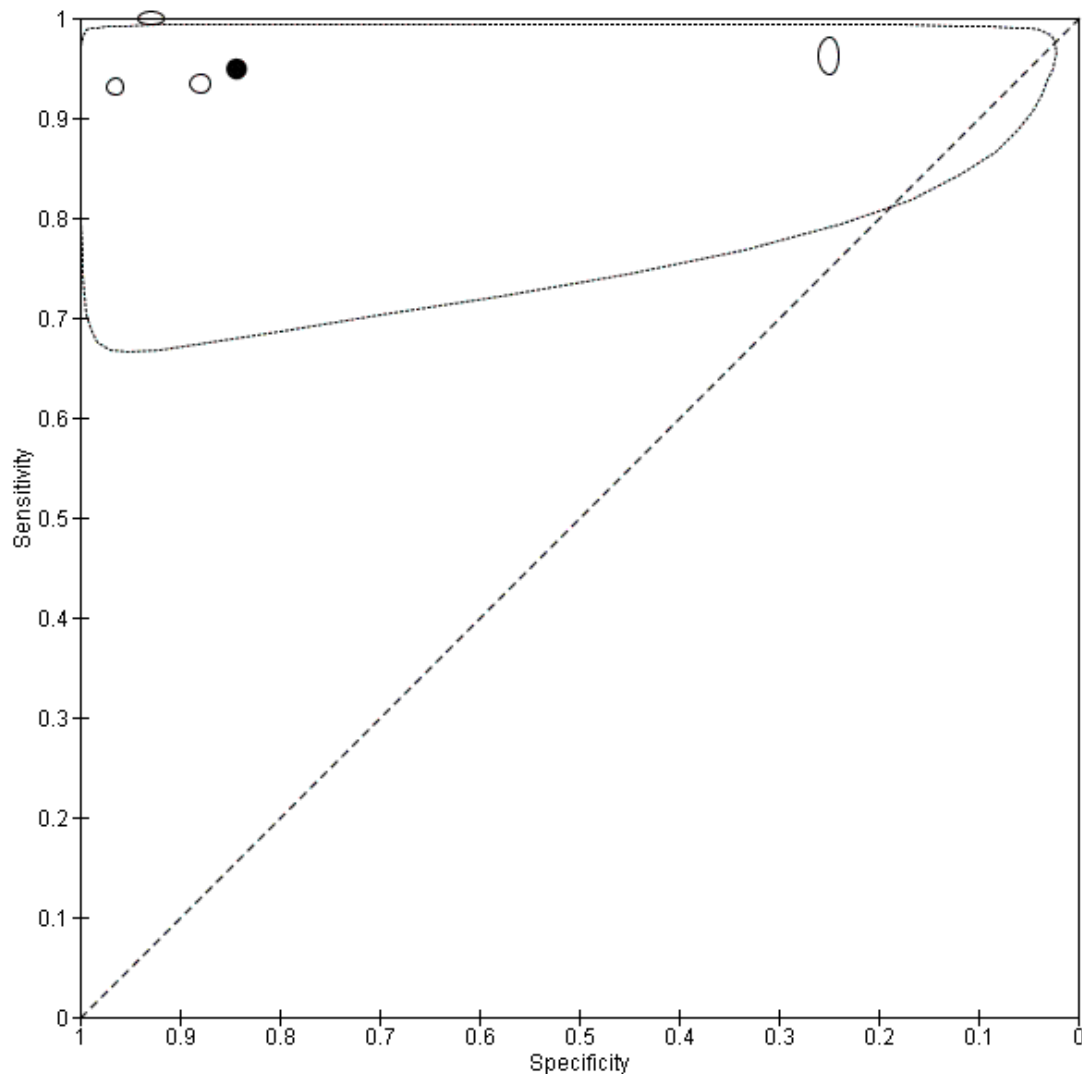

Figure 7. Summary receiver operating characteristic plot of teledermatology using photographic images versus histology for the detection of any skin cancer (any).

Four studies compared diagnosis based on photographic images to histology (Figure 6). In three studies, sensitivities for the correct diagnosis of malignancy ranged from 93% (95% CI 77% to 99%) to 100% (95% CI 75% to 100%) and specificities from 88% (95% CI 77% to 95%) to 96% (95% CI 82% to 100%) (Jolliffe 2001a; Kroemer 2011; Moreno Ramirez 2005). All three studies reported a cross-tabulation of lesion final diagnoses against the diagnosis on teledermatology such that data could be extracted for the detection of any malignancy, regardless of any misclassification of one skin cancer for another (e.g. a BCC diagnosed as

a melanoma or vice versa). Similarly there was high sensitivity in Silveira 2014 (96%, 95% CI 94% to 98%) but specificity was outlying at 25% (95% CI 14% to 39%); data here were presented for the detection of 'malignant' versus benign cases with no breakdown of individual lesion diagnoses given. The low specificity in Silveira 2014 result was likely due to the recruitment of participants with lesions deemed to be highly clinically suspicious after visual inspection of the lesion during a community screening programme; the prevalence of malignancy was 87.5% with only 52 benign cases in a sample of 416 lesions.

The pooled result across the four studies indicated a summary sensitivity of 94.9% (95% CI 90.1% to 97.4%) and summary specificity of 84.3% (95% CI 48.5% to 96.8%) based on 717 lesions and 452 cases of skin cancer (Table 2; Figure 7).

One study also reported diagnosis based on dermoscopic images only versus histology (Kroemer 2011). Sensitivity was lower than for assessment using photographic images (85%, 95% CI 71% to 94% with histology versus 93%, 95% CI 82% to 99% with dermoscopic images) with similar specificities (Figure 6).

Three studies with 928 lesions and 215 cases of skin cancer compared image-based diagnosis based on both clinical and dermoscopic images to histology (Figure 6). Each study used a slightly different threshold to decide test positivity: the correct classification of lesions as malignant versus benign (Massone 2014), lesions considered malignant or possibly malignant (Borve 2015), or lesion recommended for excision (Arzberger 2016). Sensitivities were 100% in all three studies. Specificities ranged from 25% (95% CI 5% to 57%) (Arzberger 2016) to 92% (95% CI 74% to 99%) (Massone 2014). Massone 2014 was a primary care-based study for which accuracy data could only be estimated for a subgroup of 32 of the original 962 lesions. Arzberger 2016 included participants at particularly high risk for melanoma, while Borve 2015 included large proportions of seborrhoeic keratosis (19%) and actinic keratosis (9%) in the disease-negative group. These

factors may have made differentiating a malignant case from a benign one more challenging.

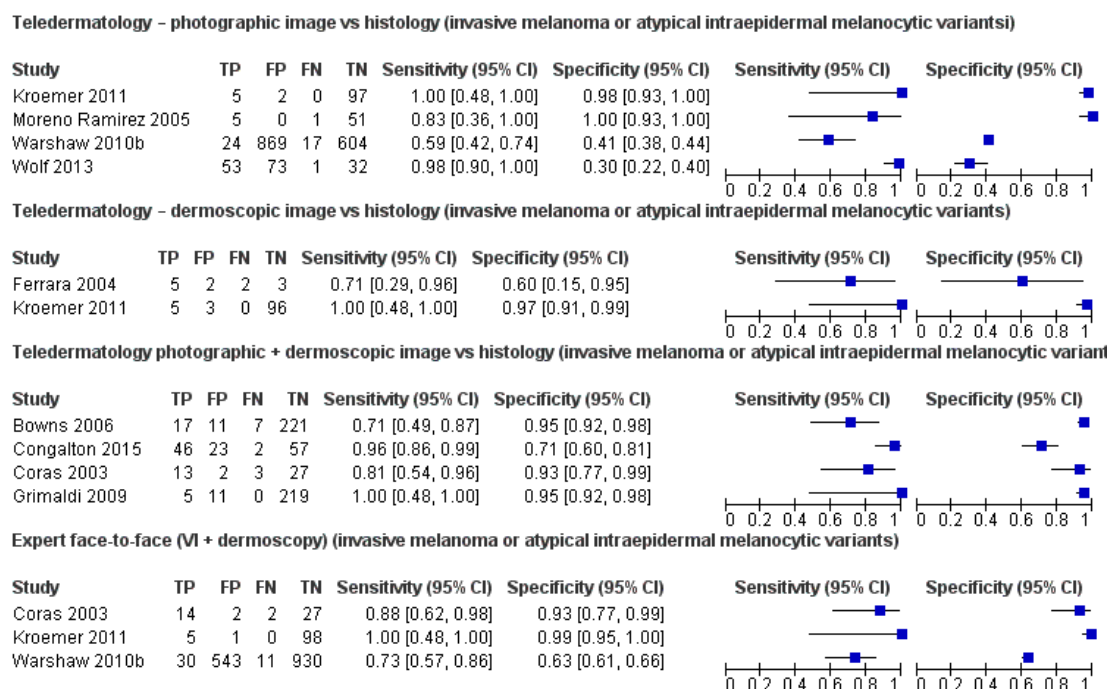

We undertook no statistical pooling for these studies due to variation in threshold and heterogeneity in specificities.

Two studies compared remote image-based assessment with in-person diagnosis by a dermatologist for the detection of any skin cancer using the same diagnostic thresholds as for the teledermatology decision (Jolliffe 2001a; Kroemer 2011). Jolliffe 2001a reported 100% (95% CI 75% to 100%) sensitivity for both assessments, while Kroemer 2011 reported 100% (95% CI 92% to 100%) sensitivity for in-person diagnosis compared to 93% (95% CI 82% to 99%) for diagnosis using photographic images and 85% (95% CI 71% to 94%) for dermoscopic image-based assessment (Table 3; Figure 6). Both studies reported only marginal differences in specificity between approaches.

2. Target condition: invasive melanoma or atypical intraepidermal melanocytic variants

Nine studies with 2510 lesions and 206 melanoma reported the diagnostic accuracy of teledermatology assessment for the detection of invasive cutaneous melanoma or atypical intraepidermal variants (Figure 8), only two of which also reported data for the detection of any skin cancer (Table 2).

Figure 8. Forest plot of tests for the detection of invasive melanoma or atypical intraepidermal melanocytic variants. CI: confidence interval; FN: false negative; FP: false positive; TN: true negative; TP: true positive; VI: visual inspection.

In four studies with 1834 lesions and 106 melanomas comparing diagnosis based on photographic images to histology, sensitivities ranged from 59% (95% CI 42% to 74%) to 100% (95% CI 48% to 100%) and specificities from 30% (95% CI 22% to 40%) to 100% (95% CI 93% to 100%) (Kroemer 2011; Moreno Ramirez 2005; Warshaw 2010b; Wolf 2013). In three studies, the data extracted were for the correct diagnosis of melanoma whereas in Wolf 2013, lesions were classified as 'atypical' or 'typical' as opposed to reporting the correct diagnosis of melanoma. The difference in the diagnostic decision recorded in Wolf 2013 is likely to account for the low specificity observed.

The relatively low sensitivity and specificity observed in Warshaw 2010b is difficult to explain but may be related to differences in population characteristics between studies. Two studies restricted inclusion to pigmented lesions considered clinically atypical by at least one dermatologist (Wolf 2013), or meeting explicit criteria that might suggest a higher risk for melanoma (Moreno Ramirez 2005). Wolf 2013 selecting specific lesion types and excluding those with an equivocal diagnosis. Kroemer 2011 included participants with any lesion type who were either self-referred or referred by a local doctor to a general dermatology clinic. Warshaw 2010b

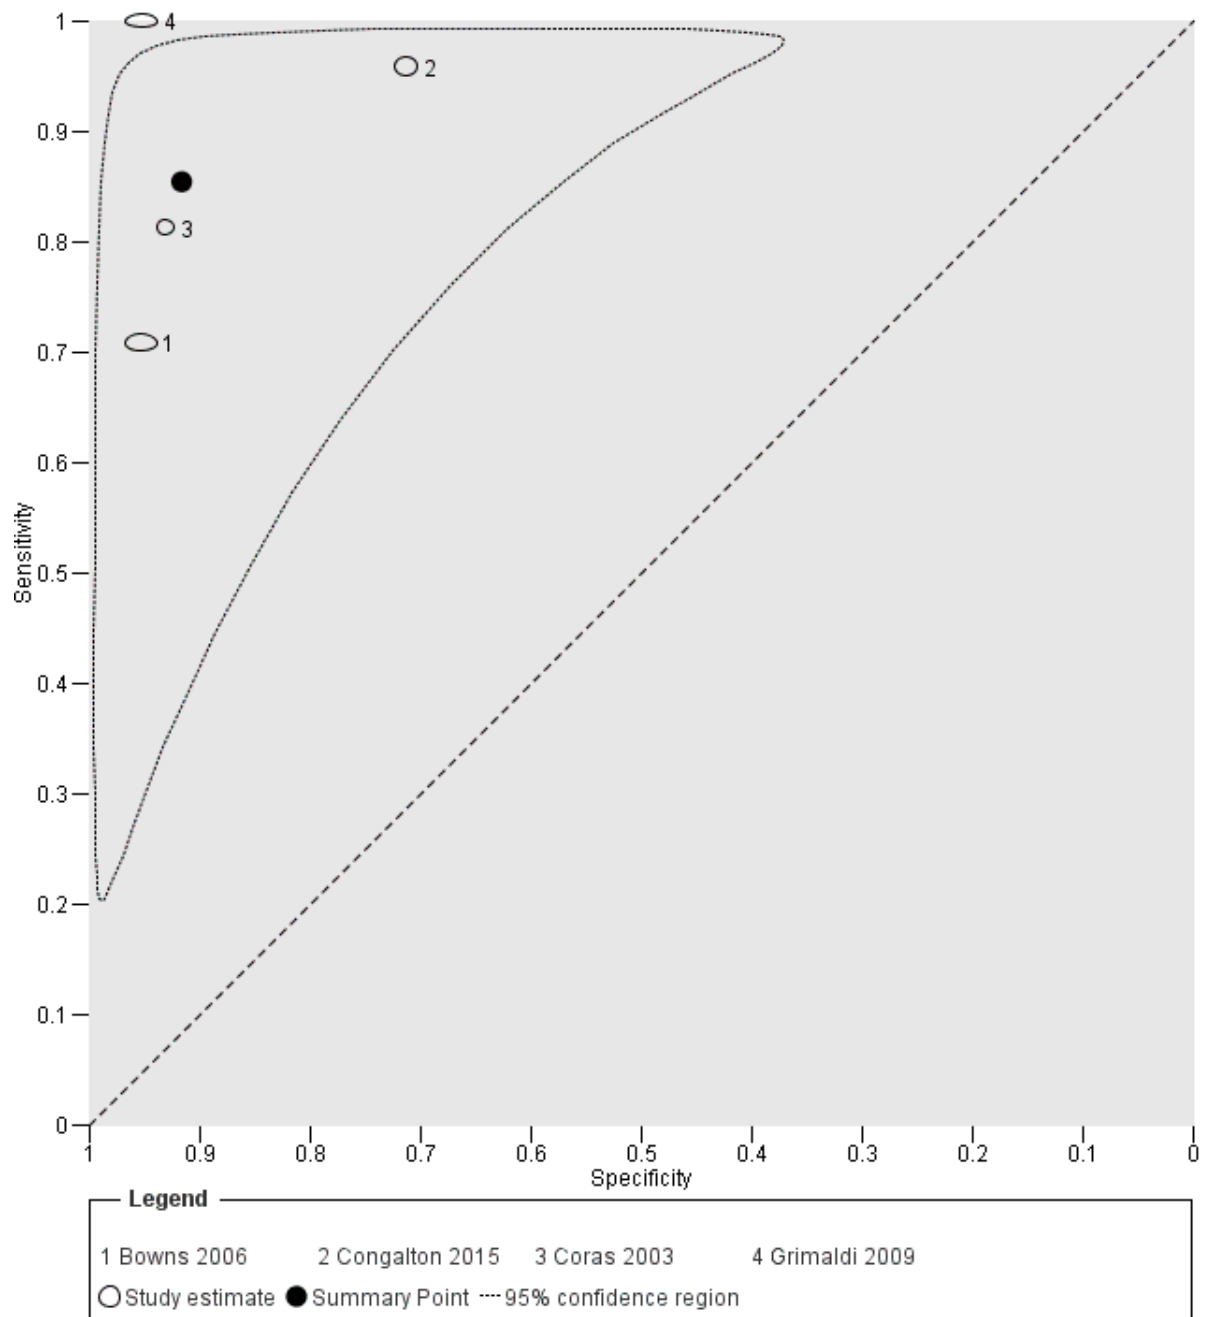

also included any lesion type (pigmented or non-pigmented) from participants who required or requested removal of one or more skin lesions (denoted 'high risk' by the study authors) or from people who were referred by non-dermatology healthcare providers for specialist assessment (denoted as 'lower risk'); furthermore, lesions in 30 histopathological categories with fewer than 25 lesions were excluded (171 lesions).

Two studies compared dermoscopic image-based diagnosis to histology (Ferrara 2004; Kroemer 2011). Sensitivities were 71% (95% CI 29% to 96%; Ferrara 2004) and 100% (95% CI 48% to 100%; Kroemer 2011) and specificities were 60% (95% CI 15% to 95%; Ferrara 2004) to 97% (95% CI 91% to 99%; Kroemer 2011). Ferrara 2004 reported sensitivity of 71% (95% CI 29% to 96%) and specificity 60% (95% CI 15% to 95%) for the correct differentiation of seven melanomas from five benign lesions. Kroemer 2011 reported very similar sensitivity and specificity for the correct diagnosis of melanoma using only dermoscopic images to their result using non-magnified photographic images: sensitivities with both approaches were 100% (95% CI 48% to 100%) while specificities were 98% (95% CI 96% to 100%) using photo-

graphic images compared to 97% (95% CI 91% to 99%) for dermoscopic images. Data were not presented for diagnosis using both clinical and dermoscopic images; however, the study reported that “re-evaluation of both image types in (discordant cases) did not improve the diagnostic accuracy of teleconsultations” (Kroemer 2011).

Four studies with 664 lesions and 93 cases of melanoma or atypical intraepidermal melanocytic variants compared teledermatology based on both clinical and dermoscopic images to histology (Bowns 2006; Congalton 2015; Coras 2003; Grimaldi 2009). Summary estimates of sensitivity were 85.4% (95% CI 68.3% to 94.1%) and specificity 91.6% (95% CI 81.1% to 96.5%) (Table 2; Figure 9).

Figure 9. Summary receiver operating characteristic plot of teledermatology using clinical and dermoscopic images for the detection of invasive melanoma or atypical intraepidermal melanocytic variants.

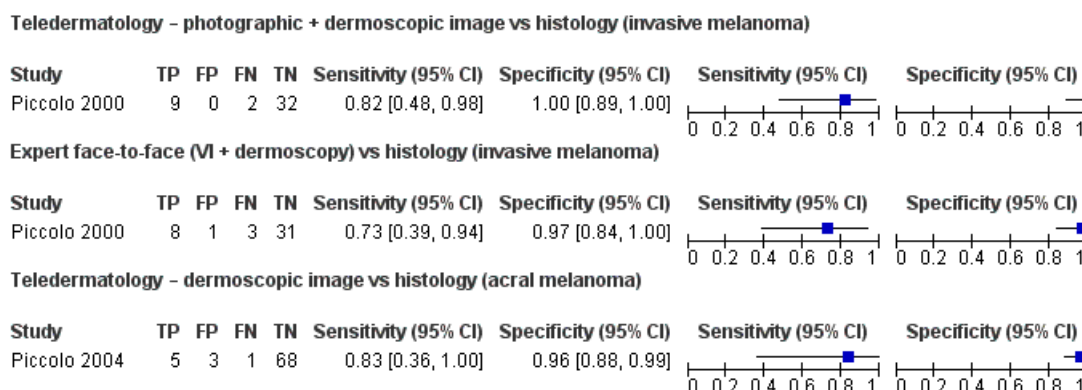

Across the 10 teledermatology datasets, the number of melanomas missed ranged from 0 (two datasets, both from [Kroemer 2011](#)) to 17 ([Warshaw 2010b](#)).

Three studies in this group compared teledermatology assessment of images to face-to-face diagnosis by a dermatologist ([Coras 2003](#); [Kroemer 2011](#); [Warshaw 2010b](#)) ([Table 3](#)). In [Warshaw 2010b](#), the diagnostic accuracy of teledermatology diagnosis of melanoma using photographic images and patient history was considerably lower compared to an in-person dermatologist diagnosis (using visual inspection with or without the use of dermoscopy as determined by the individual clinician); data from the author showed that sensitivity was 15% lower for teledermatology assessment (95% CI -33% to 6%) and specificity was 22% lower (95% CI -26% to -19%) ([Table 3](#)). The accuracy of the expert face-to-face diagnosis was nevertheless relatively low, with sensitivity of 73% (95% CI 57% to 86%) and specificity of 63% (95% CI 61% to 66%) ([Figure 8](#)). The two studies comparing teledermatology diagnosis using both macro and dermoscopic images demonstrated only marginal differences between the two approaches ([Coras 2003](#); [Kroemer 2011](#)) ([Table 3](#)).

3. Target condition: invasive cutaneous melanoma

[Piccolo 2000](#) with 43 lesions reported the diagnostic accuracy of teledermatology assessment for the detection of invasive melanoma selected for their 'diagnostic difficulty' (11 cases of melanoma) and [Piccolo 2004](#) for the differentiation of six acral melanoma from 71 benign acral lesions ([Figure 10](#)). In [Piccolo 2000](#), the sensitivity for store-and-forward teledermatology assessment was 82% (95% CI 48% to 98%) and specificity was 100% (95% CI 89% to 100%) in comparison to in-person dermatologist assessment of the same lesions where sensitivity was 73% (95% CI 39% to 94%) and specificity 97% (95% CI 84% to 100%) (one invasive melanoma missed in the face-to-face encounter was identified using teledermatology). Similar teledermatology accuracy (based on a consensus of six out of 11 observers) was obtained for acral lesions in [Piccolo 2004](#) using only dermoscopic images: observed sensitivity was 83% (95% CI 36% to 100%) and specificity was 96% (95% CI 88% to 99%).

Figure 10. Forest plot of tests for the detection of invasive melanoma. CI: confidence interval; FN: false negative; FP: false positive; MM: malignant melanoma; TN: true negative; TP: true positive; VI: visual inspection.

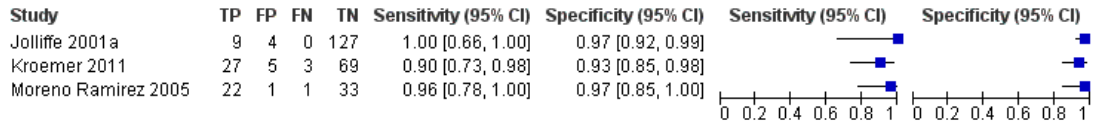

4. Target condition: BCC

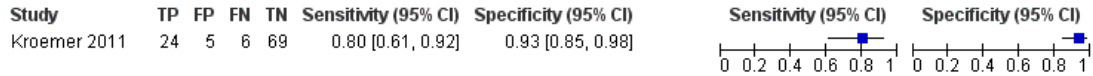

Four studies reported the diagnostic accuracy of teledermatology assessment for the detection BCC ([Figure 11](#); [Figure 12](#)).

Figure 11. Forest plot of tests for the detection of basal cell carcinoma (BCC). CI: confidence interval; FN: false negative; FP: false positive; TN: true negative; TP: true positive.

Teledermatology – photographic + dermoscopic image vs histology (BCC)

Expert face-to-face (VI + dermoscopy) vs histology (BCC)

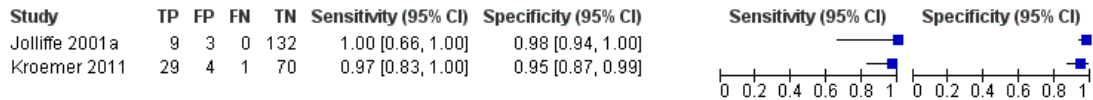

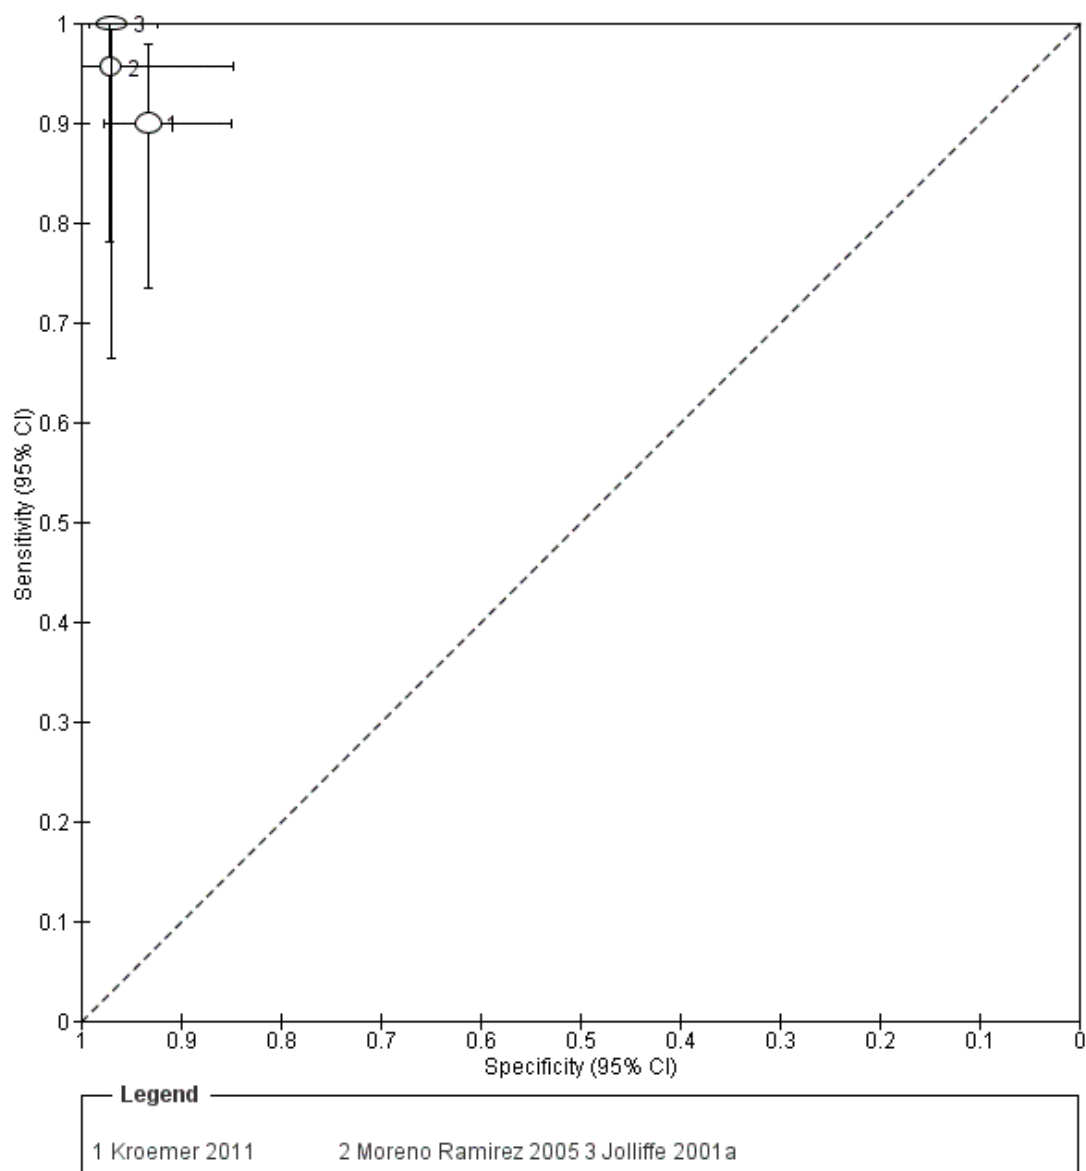

Figure 12. Receiver operating characteristic plot teledermatology using photographic images alone versus histology for the detection of basal cell carcinoma.

Three evaluations of photographic images for 301 lesions with 62 cases of BCC (Jolliffe 2001a; Kroemer 2011; Moreno Ramirez 2005), produced summary estimates of sensitivity of 93.5% (95% CI 84.0% to 97.6%) and specificity 95.8% (95% CI 92.4% to 97.7%) (Table 2; Figure 12). Four BCCs were missed in two studies (Kroemer 2011; Moreno Ramirez 2005).

One study reported lower sensitivity using dermoscopic images (80%, 95% CI 61% to 92%) compared to photographic images (90%, 95% CI 73% to 98%), due to an additional two BCCs being mistaken for actinic keratosis (Kroemer 2011). A further study reporting data only for teledermatology using clinical and dermoscopic images also reported low sensitivity for BCC of 66% (95% CI 46% to 82%) (Bowns 2006). Both studies reported specificities of 93% and over (Figure 11).

Two studies provided a comparison with expert face-to-face as-

essment (Table 3). Kroemer 2011 reported higher sensitivity and specificity in the face-to-face assessments and Jolliffe 2001a reported almost identical sensitivity and specificity estimates from the two approaches.

5. Target condition: cutaneous squamous cell carcinoma

Kroemer 2011 reported accuracy for the detection of cSCC in 104 lesions with 10 cases of cSCC. There was a sensitivity of 90% (95% CI 55% to 100%) (one cSCC missed) for diagnosis based on photographic images and for the face-to-face assessments, with a sensitivity of 60% (95% CI 26% to 88%) (four cSCCs missed) for remote assessment based on dermoscopic images (Figure 13). Specificities were over 98% for all three approaches to diagnosis.

Figure 13. Forest plot of tests for the detection of cutaneous squamous cell carcinoma (cSCC). CI: confidence interval; FN: false negative; FP: false positive; TN: true negative; TP: true positive; VI: visual inspection.

Teledermatology – photographic image vs histology (cutaneous squamous cell carcinoma (cSCC))

Study	TP	FP	FN	TN	Sensitivity (95% CI)	Specificity (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)

Kroemer 2011	9	2	1	92	0.90 [0.55, 1.00]	0.98 [0.93, 1.00]		

6. Referral accuracy

Six studies gave information on diagnostic decision making by teledermatology consultants compared to expert face-to-face decisions (as the reference standard) (Figure 14).

Figure 14. Forest plot of tests for referral accuracy (expert in-person diagnosis as reference standard). CI: confidence interval; FN: false negative; FP: false positive; TN: true negative; TP: true positive.

Four studies reported data for store-and-forward teledermatology using photographic images, for the diagnosis of malignancy (Oliveira 2002), for the decision to excise a lesion (Mahendran 2005; Shapiro 2004), for the decision to refer versus not refer (Jolliffe 2001b), or to excise or follow-up at a later date (Mahendran 2005). Jolliffe 2001b reported data both for teledermatology by a dermatologist and by a dermatology registrar. It was not possible to pool results across these studies due to heterogeneity in the teledermatology.

Two studies found perfect or almost perfect agreement between teledermatology and face-to-face consultation (sensitivities 100%

and specificities 98% to 100%; Oliveira 2002; Shapiro 2004), while Mahendran 2005 also reported 100% sensitivity both for the decision to excise a lesion and the decision to excise or follow-up (Figure 14). In Jolliffe 2001b, the sensitivity of teledermatology by the dermatologist was 69% (95% CI 61% to 77%), with 44 lesions recommended for face-to-face consultation 'missed' by the remote observer, compared to 92% for the registrar's teledermatology assessment (12 lesions 'missed').

Specificities were more variable with 69% (95% CI 55% to 81%) and 57% (95% CI 39% to 73%) reported in Mahendran 2005 for

the decision to excise a lesion and the decision to excise or follow-up a lesion and 85% (95% CI 82% to 87%) and 67% (95% CI 63% to 70%) reported in [Jolliffe 2001b](#) for the dermatologist and dermatology registrar for the decision to refer a lesion. The number of lesions recommended for some action by the teledermatologist that were not recommended for action by the face-to-face expert in these studies ranged from 16 ([Mahendran 2005](#)) to 217 ([Jolliffe 2001b](#)).

[Manahan 2015](#) reported the sensitivity and specificity of the teledermatologist's decision to recommend a lesion for face-to-face consultation based on macro and dermoscopic images compared to the same recommendation by the face-to-face dermatologist (301 lesions; 35 recommended for face-to-face consultation): the resulting sensitivity was 91% (95% CI 77% to 98%) with three lesions 'missed' and specificity was 89% (95% CI 85% to 93%) with 28 lesions recommended for a face-to-face visit that were not selected by the in-person dermatologist.

Finally, [Phillips 1998](#) reported data for the accuracy of live-link teledermatology using videoconferencing compared to a dermatologist's face-to-face decision (as the reference standard) for 107 lesions. Data were reported at three different thresholds: for the correct diagnosis of a skin cancer (melanoma, BCC or cSCC), for the classification of a lesion as definitely or probably malignant and for the decision to biopsy a lesion. Sensitivities were 67% (95% CI 22% to 96%) for correct diagnosis, 60% (95% CI 15 to 95%) for definitely or probably malignant and 82% (95% CI 48 to 98%) for decision to biopsy a lesion. Specificities were 96% (95% CI 90 to 99%) for both the correct diagnosis of a skin cancer and lesions definitely or probably malignant and 86% (95% CI 78 to 93%) for decision to biopsy a lesion.

Investigations of heterogeneity

We were unable to undertake planned formal investigations of heterogeneity due to insufficient number of studies.

DISCUSSION

Although in some countries teledermatology services may provide recommendations to allow skin cancer management (including biopsy or excision) in a primary care setting, in the UK teledermatology consultations for the most part ensure that people with potentially malignant skin lesions are appropriately referred from a generalist (usually primary care) setting for specialist assessment and treatment. Therefore, the primary objective of this review was to assess the accuracy of teledermatology for the detection of any skin cancer in adults, comparing its accuracy with that of an in-person specialist diagnosis.

Summary of main results

We included 22 studies: 16 considering the diagnostic accuracy of image-based teledermatology (five in comparison to an in-person assessment), and six examining the referral accuracy of teledermatology assessment. Key results are presented in the [Summary of findings](#). The overall risk of bias was rated as high or unclear for participant selection, reference standard, and participant flow and timing in at least half of all studies; the majority were considered at low risk of bias for the index test. The applicability of study findings were of high or unclear concern for most studies in all domains assessed due to the recruitment of study participants from secondary care settings or specialist clinics rather than from the primary or community-based settings in which teledermatology is more likely to be used and due to the acquisition of lesion images by dermatologists or in specialist imaging units rather than by primary care clinicians.

Seven studies addressed our primary objective of the detection of any skin cancer. For the correct diagnosis of lesions as malignant, summary sensitivity from four studies using photographic images was 94.9% (95% CI 90.1% to 97.4%) and summary specificity 84.3% (95% CI 48.5% to 96.8%). Individual study estimates using dermoscopic images or a combination of photographic and dermoscopic images generally suggested similarly high sensitivities with highly variable specificities. Limited comparative data suggested similar diagnostic accuracy between teledermatology assessment and in-person diagnosis by a dermatologist; however, data were too scarce to draw firm conclusions.

For the detection of invasive melanoma or atypical intraepidermal melanocytic variants, both sensitivities and specificities were very variable, with reported diagnostic thresholds including the correct diagnosis of melanoma, classification of lesions as 'atypical' or 'typical', and the decision to refer or to excise a lesion. For teledermatology using photographic images, sensitivities ranged from 59% (95% CI 42% to 74%) to 100% (95% CI 48% to 100%) and specificities from 30% (95% CI 22% to 40%) to 100% (95% CI 93% to 100%) in four studies. For teledermatology using both photographic and dermoscopic images summary estimates for another four studies were 85.4% (95% CI 68.3% to 94.1%) for sensitivity and 91.6% (95% CI 81.1% to 96.5%) for specificity. The number of melanomas missed ranged from 0 to 17.

Referral accuracy data comparing teledermatology against a face-to-face reference standard was based on a number of different diagnostic decisions including the diagnosis of malignancy, the decision to excise a lesion, the decision to refer versus not refer, or to excise or follow-up at a later date. Agreement was generally good for lesions considered to require some positive action by face-to-face assessment (sensitivities of over 90%). For lesions considered of less concern when assessed face-to-face (e.g. for those not recommended for excision or referral), agreement was more variable with teledermatology specificities ranging from 57% (95% CI 39% to 73%) to 100% (95% CI 86% to 100%), suggesting that remote assessment is more likely recommend excision, referral or follow-up compared to in-person decisions.

Across all studies, there were wide variations in sensitivity and specificity for all definitions of the target condition. Studies were generally small with varying approaches to teledermatology assessment, including the use of clinical or dermoscopic images (or both); use of mobile phone cameras, digital cameras or video images; and varying thresholds for deciding test positivity. The definition of the target condition also varied such that data for the primary objective could only be extracted from seven of the 16 studies assessing diagnostic accuracy, nine studies reporting data only for the detection of individual skin cancers. These factors somewhat limited our ability to pool results across studies and further, to draw conclusions regarding the accuracy of teledermatology. Overall, there were four key limitations of the studies.

- The spectrum (or case mix) of different lesion types varied across studies, with a relatively high prevalence of malignant lesions.

Study participants were largely recruited from secondary care settings or from pigmented lesion clinic databases rather than from primary care or other limited prior testing settings and 50% of the studies assessing diagnostic accuracy relied on a histological reference standard (i.e. all included participants underwent lesion excision). In others, accuracy data could be extracted for less than 25% of lesions assessed at a virtual lesion clinic (Congalton 2015), or as part of a preventive medical screening programme (Massone 2014). Therefore, recruited participants were more likely to have lesions with a higher index of suspicion of malignancy compared to those for whom a GP might have considered a teledermatology assessment in practice, thereby limiting the generalisability of study results. These 'spectrum effects' are an increasingly recognised concept for medical tests, often leading to lower sensitivity and higher specificity when applied in settings with participants with limited prior testing compared to participants further down the referral pathway (Usher-Smith 2016). However, the direction of effect is not consistent across tests and diseases (Leeftang 2013), the mechanisms in action often being complex and sometimes difficult to identify.

- Study definitions of 'malignancy' varied and teledermatology results were often not provided according to lesion type.

In four included studies, the reported definition of malignancy did not accord with our protocol-defined definition, with studies including melanoma metastases, Bowens disease or 'in situ cSCC', actinic keratosis or severely dysplastic naevi as 'malignant.' In some cases, data were reported to allow reclassification of these lesions as disease negative for at least some of the reported thresholds for test positivity (Borve 2015; Massone 2014); however, for others, reclassification of these lesions as disease positive was not possible and these studies could only be included in our analyses for the detection of individual skin cancers (melanoma or BCC) (Bowens 2006; Congalton 2015). Other studies had to be excluded from the review altogether due to varying definitions of 'malignant' (e.g.

Borve 2013; Tandjung 2015). The lack of teledermatology results according to lesion type further limited our ability to comment on the implications of missed malignancies; the failure to pick up a melanoma or cSCC potentially carrying more severe consequences in comparison to a missed BCC.

- The definition of a positive teledermatology result varied and was not always relevant to decision making in practice.

Of the 16 diagnostic accuracy studies, only three studies reported data for the decision to excise a lesion (one for any skin cancer and two for the detection of melanoma), and five reported data for teledermatologists' classification of lesions as malignant (or probably malignant). Nine of the 16 studies focused on teledermatologists' ability to correctly diagnose lesions as melanomas (eight lesions) or as BCCs (four lesions) which, although of interest, is not the primary factor driving teledermatology decisions in practice where the key judgement in most circumstances is whether or not a lesion should be referred for a face-to-face consultation.

- Insufficient comparisons were available for the diagnostic accuracy of teledermatology-based diagnosis and diagnosis based on a face-to-face dermatology clinic visit.

Only five of the 16 studies assessing diagnostic accuracy included a comparison of teledermatology-based diagnosis with diagnosis based on in-person diagnosis by a dermatologist; two for the detection of any skin cancer (Jolliffe 2001a; Kroemer 2011), and three for the detection of melanoma (Jolliffe 2001a; Kroemer 2011; Piccolo 2000). Therefore, we were unable to adequately assess whether a teledermatology diagnosis of malignancy accurately reflects a diagnosis made in-person. The six studies of referral accuracy suggested that diagnosis of individual lesions using store-and-forward teledermatology could miss around 10% of lesions recommended for clinical action (e.g. surgical excision) during a face-to-face consultation (even up to 31% in one study) and is also likely to recommend an action is required for lesions that are considered of less or no concern when seen in-person. In practice, a face-to-face consultation also allows a total body skin examination which may lead to incidental skin cancers being picked up which could also be missed by the teledermatology referral of only one or two lesions (Hanson 2016).

Our systematic review of dermoscopy as an addition to visual inspection of a lesion for the diagnosis of melanoma found in-person dermoscopy (including 26 studies) to be substantially more accurate compared to diagnosis based on dermoscopic images (including 60 studies) (relative diagnostic odds ratio 4.6, 95% CI 2.4 to 9.0; $P < 0.001$) (Dinnes 2018a). Despite a number of contributing factors, including differences in study populations, different algorithms to assist test interpretation and differences in observer experience, we concluded that remote test interpretation cannot approximate a physical, face-to-face patient-to-clinician interaction. In particular, total body skin examination is likely to have a significant impact on the decision to excise a lesion suspected to be melanoma (Aldridge 2013; Argenziano 2012; Grob 1998). Only

two of the 22 included teledermatology studies mentioned the use of total body photography (Arzberger 2016; Phillips 1998). It is notable also, that across the 60 image-based evaluations in the review of dermoscopy, 30 (50%) were blinded to all other participant information and only 17 (28%) provided observers with the photographic image of the same lesion to assist test interpretation (Dinnes 2018a). It is conceivable that an image-based assessment with full patient information provided in the context of a proper teledermatology consultation would provide a closer approximation of the diagnostic decision that would be made with the patient present.

Strengths and weaknesses of the review

The strengths of this review include an in-depth and comprehensive electronic literature search, systematic review methods including double extraction of papers by both clinicians and methodologists, and contact with authors to allow study inclusion or clarify data. A clear analysis structure was planned to allow test accuracy to be estimated according to varying definitions of the target condition and a detailed and replicable analysis of methodological quality was undertaken.

The main concerns for the review were the lack of studies, small sample sizes, heterogeneity in teledermatology assessments, inadequate reporting of primary studies to allow quality to be fully judged and importantly, the lack of clinical applicability of the findings due to participant recruitment from, and image acquisition in, referral settings.

In comparison to other available systematic (Ndegwa 2010; Warshaw 2011) and non-systematic (Bashshur 2015; Whited 2006; Whited 2016) reviews, our review provides a focus on the triaging or diagnosis of skin cancer as opposed to the evaluation of teledermatology for any dermatological disorder. The two most recently published reviews either found evidence generally in support of teledermatology (Bashshur 2015), or suggesting inferior accuracy compared to in-person assessments for pigmented lesions (Whited 2016). In contrast we were unable to identify sufficient evidence to establish the diagnostic accuracy of teledermatology in comparison to a face-to-face clinical assessment. Our reviews of the diagnostic accuracy of visual inspection of suspicious skin lesions for the detection of melanoma (Dinnes 2018b), and of dermoscopy in comparison to visual inspection of a suspicious skin lesion (Dinnes 2018a), suggest that image-based assessment may not be equivalent to a face-to-face patient:clinician interaction. However, both reviews focused on the correct diagnosis of melanoma as opposed to any skin cancer, neither included studies that were specifically designed to evaluate teledermatology programmes and did not examine any effect on accuracy from potential improvements in image quality over time.

Our a priori decision to exclude studies with fewer than five malignant cases could be construed as a weakness of the review; however, of the seven studies excluded on this basis, five were also

excluded due other reasons such as inability to construct a 2x2 contingency table or ineligible study populations and one used multiple images of only four lesions to examine the effect of the positioning of a lesion within an image on clinicians ability to detect it (Chen 2002). The final study which was excluded only on the basis of sample size reported the effect of adding dermoscopic images to an existing teledermatology consultation system for 63 lesions fulfilling the criteria for teleconsultation (Moreno-Ramirez 2006); all three malignant lesions were correctly picked up using both photographic images and with the addition of dermoscopic images (100% sensitivities) while specificities were 65% with photographic images and 78% with photographic and dermoscopic images.

We were also unsuccessful in our attempts to contact the authors of eight of 12 studies which could have been eligible for inclusion in the review, especially those studies which reported only agreement between observers or agreement with final lesion diagnoses rather than providing results in a 2x2 contingency table format. Furthermore, only partial data were provided to allow the inclusion of one study in the review (Warshaw 2010b); the review would be considerably strengthened if data for teledermatology using dermoscopic images could have been included. Finally, the review was limited to the identification of skin cancer rather than assessing the potential additional benefits of teledermatology such as positive identification of benign lesions such as actinic keratosis (Janda 2015).

Ongoing technological advances are continually improving the quality, clarity and colour-rendition of digital images taken with cameras and mobile phones. The ability to zoom in on new larger image files potentially provides even more detailed information compared to observation of a lesion with the naked eye alone. Such advances could be of particular help in the triage of lesions with no distinguishing features (e.g. for the identification of amelanotic melanomas), the additional magnification potentially giving subtle clues to aid diagnosis. Although we have documented the equipment used to obtain images in the included studies, we were unable to identify any clear effects from changes in technology. Our review of the diagnostic accuracy of teledermatology was also unable to evaluate a number of other pertinent factors.

- The archiving and auditable trail provided by a teledermatology consultation. With conventional face-to-face consultations, much of the interchange is verbal and unrecorded; for teleconsultation however, every aspect of the referral and diagnostic opinion are recorded such that it can be reviewed and audited at a later date.

- The possibility of 'crowd-review' of lesion images. In-person clinical assessment is often conducted by a single clinician, consultation with other qualified clinicians reserved for more difficult lesions or to support more junior clinicians. The nature of teledermatology diagnosis lends itself to lesion review by multiple clinicians and to have virtual multidisciplinary review of cases if necessary.

- Changing the referral behaviour of primary care clinicians. The availability of a teledermatology service could result in a specialist opinion being sought for much earlier presentations of conditions than would normally be the case, which not only changes the spectrum of lesion types observed by teledermatologists, potentially impacting on their accuracy, but could ultimately result in overdiagnosis and treatment. For example, some lesions identified and either excised or treated non-surgically following a teleconsultation might have resolved spontaneously if monitored for longer in primary care, or if referred for a standard face-to-face consultation. The effect on referral behaviour is likely to be exacerbated where ease of access to a teledermatology service for a specialist opinion may be preferred by GP trainees to seeking the opinion of a more experienced GP.

- Possible over-reliance by GPs and reassurance for patients on a benign diagnosis from a teledermatology consultation. As with all clinical consultations, a diagnostic opinion from a teledermatology consultation is limited to the quality of the clinical information provided and the circumstances at the time of consultation. If those circumstances change, for example if a pigmented lesion diagnosed as 'benign' evolves or changes its nature in some way, then that lesion should be reviewed. 'Safety-netting' such lesions is an important part of management and monitoring in primary care.

Applicability of findings to the review question

The data included in this review are unlikely to be generally applicable to the intended setting. Most studies recruited participants from secondary care or referral settings rather than from primary care settings where patients are far less likely to have skin cancer, and potentially suspicious lesions are likely to be earlier in their development and evolution. Lesion images were often acquired in secondary care rather than being acquired in primary care and transmitted for a specialist opinion using teledermatology. Considerable heterogeneity in approaches to teledermatology were also observed limiting generalisability.

AUTHORS' CONCLUSIONS

Implications for practice

Studies were generally small and heterogeneous and methodological quality was difficult to judge due to poor reporting. Considering concerns regarding the applicability of study participants and of lesion image acquisition in specialist settings, our results suggest that teledermatology can be relied upon to correctly identify most malignant lesions. Using a more widely defined threshold to identify 'possibly' malignant cases or lesions that should be considered

for excision is likely to appropriately triage those lesions requiring face-to-face assessment by a specialist.

Implications for research

Despite the increasing use of teledermatology on a national and international level, the evidence base to support its ability to accurately triage lesions from primary to secondary care is lacking and further prospective and pragmatic evaluation is needed. Consecutive series of participants with suspicious skin lesions judged to require a specialist opinion by general practitioners should be recruited (i.e. excluding those clearly judged to be malignant or benign) and referred for store-and-forward teledermatology in comparison to routine referral to a dermatologist. The reason for referral (e.g. exclusion of melanoma to avoid an urgent or 'two-week wait' referral, exclusion of cSCC or basal cell carcinoma, or exclusion of 'any skin cancer') should be clearly recorded. 'State-of-the-art' digital photography should be used (potentially utilising mobile phone cameras) to allow the full benefit of current technology to be exploited, and compared with smart phone applications, and systematic follow-up of non-excised lesions implemented to avoid over-reliance on a histological reference standard. The level of training and experience of both the referring and specialist clinicians should be explicit to allow the generalisability of results to be judged. Any future research study needs to be clear about the diagnostic pathway followed by study participants, and should conform to the updated Standards for Reporting of Diagnostic Accuracy (STARD) guideline (Bossuyt 2015).

ACKNOWLEDGEMENTS

Members of the Cochrane Skin Cancer Diagnostic Test Accuracy Group include:

- the full project team (Susan Bayliss, Naomi Chuchu, Clare Davenport, Jonathan Deeks, Jacqueline Dinnes, Lavinia Ferrante di Ruffano, Kathie Godfrey, Rubeta Matin, Colette O'Sullivan, Yemisi Takwoingi, Hywel Williams);

- our 12 clinical reviewers (Rachel Abbott, Ben Aldridge, Oliver Bassett, Sue Ann Chan, Alana Durack, Monica Fawzy, Abha Gulati, Jacqui Moreau, Lopa Patel, Daniel Saleh, David Thompson, Kai Yuen Wong) and two methodologists (Lavinia Ferrante di Ruffano and Louise Johnston) who assisted with full-text screening, data extraction and quality assessment across the entire suite of reviews of diagnosis and staging and skin cancer;

- our expert advisors and co-authors on the review (Fiona Walter and Richard Motley) and on the protocol for keratinocyte skin cancer (Fiona Bath-Hextall); and

- all members of our Advisory Group (Jonathan Bowling, Seau Tak Cheung, Colin Fleming, Matthew Gardiner, Abhilash

Jain, Susan O'Connell, Pat Lawton, John Lear, Mariska Leeflang, Richard Motley, Paul Nathan, Julia Newton-Bishop, Miranda Payne, Rachael Robinson, Simon Rodwell, Julia Schofield, Neil Shroff, Hamid Tehrani, Zoe Traill, Fiona Walter, Angela Webster).

The Cochrane Skin Group editorial base wishes to thank Michael Bigby, who was the Dermatology Editor for this review, and the clinical referee, David De Berker. We also wish to thank the Cochrane DTA editorial base and colleagues, as well as Anne Lawson, who copy-edited this review.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Arzberger 2016

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: May to October 2009 Country: Austria
Patient characteristics and setting	Inclusion criteria: study participants with at least 1 of the following factors associated with moderate-to-high risk of melanoma: personal or first-degree relative history of melanoma; history of dysplastic naevi; > 5 atypical naevi; > 100 naevi; lesion suspicious for melanoma Setting: specialist clinic (Pigmented Skin Lesion Clinic Medical University of Graz) Prior testing: NR Setting for prior testing: NR Exclusion criteria: none reported Sample size (participants): number eligible: 70; number included: 20 Sample size (lesions): number eligible: 1922; number included: 23 Participant characteristics: Age: range: 11-81 years Gender: male: 35, female 35 Lesion characteristics: none reported
Index tests	TD Acquisition and transmission of images: after clinical examination participants had total body photography performed by an experienced dermatology nurse or dermatology resident (took on the role of a "melanographer"), images were taken using the MoleMap program, without regard of the decision made at the FTF examination. Without regard to the medical decision resulting from the F2F evaluation, the melanographer acquired body-sector photographs (Nikon D40 and D50 digital SLR, Nikon Corporation Tokyo, Japan) and photographs of selected skin lesions were those that were: "(i) highly suspicious; (ii) concerning; (iii) changing and/or different; (iv) > 3 mm; (v) itching, bleeding, inflamed; or (vi) suspicious for basal cell carcinoma (BCC) or squamous cell carcinoma." Selected lesions had a close-up macroscopic and dermoscopic image taken. Images were then uploaded to a centralised server in New Zealand, which was accessible to the participating teledermoscopy experts Nature of images used: clinical and dermoscopic Any additional participant information provided: total body images Observer qualifications (remote diagnosis): dermatologists (experts in dermoscopy) Diagnosis based on: single observer Number: 4 Method of diagnosis: 4 remote teledermoscopy experts evaluated the total body images and dermoscopic images, and gave a recommendation for each lesion Management options (diagnostic threshold): recommendations for management included: "self-monitoring," "short-term monitoring" and "excision"

Target condition and reference standard(s)	Reference standard: histology Details: <i>histology (excision)</i> Lesions were selected for excision after conventional FTF total body and dermoscopic examination of all lesions, performed by individual dermatologists with expertise in the assessment of pigmented lesions. Histopathological examination of excised lesions was performed at the Dermatopathology Laboratory at the Medical University Graz, Graz, Austria <ul style="list-style-type: none">• Number participant/lesions: 23• Disease positive: 9• Disease negative: 14 Target condition (final diagnoses) <ul style="list-style-type: none">• Melanoma (invasive): 8• Melanoma (in situ): 1• BCC: 2• Other: 12 melanocytic nevi		
Flow and timing	50 participants were excluded from the final analysis (48 participants were discharged with the recommendation to do monthly self-skin examination and 2 participants were followed up) 20 participants had their lesions excised (included in the final analysis) The interval between index test and reference standard was not clearly reported; however, it appeared to be simultaneously		
Comparative			
Notes	-		
Methodological quality			
Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Unclear		
Was a case-control design avoided?	Yes		
Did the study avoid inappropriate exclusions?	Unclear		
Are the included patients and chosen study setting appropriate?	No		
Did the study avoid including participants with multiple lesions?	Yes		
		Unclear	High

DOMAIN 2: Index Test Teledermatology			
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes		
If a threshold was used, was it pre-specified?	Yes		
Was the test applied and interpreted in a clinically applicable manner?	No		
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Unclear		
Was the test interpretation carried out by an experienced examiner?	Yes		
		Low	High
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly classify the target condition?	Yes		
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear		
For studies comparing TD/FTF clinical diagnosis to histology, was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear		
For studies comparing TD to FTF diagnosis, was the clinical diagnosis carried out by an experienced observer?			
		Low	Unclear

DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Unclear		
Did all patients receive the same reference standard?	Yes		
Were all patients included in the analysis?	No		
If the reference standard includes clinical FU of borderline/benign appearing lesions, was there a minimum FU following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?			
		High	

Borve 2015

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: January 2011 to December 2012 Country: Sweden
Patient characteristics and setting	Inclusion criteria: adults > 18 years of age with ≥ 1 skin lesions of concern requiring referral to a dermatologist using the TD referral system Setting: primary (20 primary healthcare centres in western Sweden) Prior testing: N/A Setting for prior testing: N/A Exclusion criteria: did not attend FTF visit(s), did not comply or skin lesions were located on a body part that could not be photographed Sample size (participants): number eligible: 902; number included: 816 Participant characteristics: Age: mean 54; range: 18-93 years Gender: 474 (61.3%) women Lesion characteristics: NR
Index tests	TD Acquisition and transmission of images: GPs used the smartphone TD referral system. The GP took 1 clinical and 1 dermoscopic image using an iPhone 4 with a FotoFinder Handyscope app, and

	<p>completed a standardised query form including all the relevant clinical information. This was then sent through a secure web-based TD platform (Tele-Dermis) with a secure socket layer encryption. Simultaneously the participating dermatologists received an email that a new referral was ready for assessment</p> <p>Nature of images used: clinical photographs and dermoscopic images</p> <p>Any additional participant information provided: clinical information</p> <p>Diagnosis based on: single; number of examiners: 4</p> <p>Observer qualifications (remote diagnosis): 3 specialists in dermatology and 1 resident in dermatology</p> <p>Method of diagnosis: dermatologists logged onto the Tele-Dermis platform to review the referrals on a 17- or 19-inch liquid crystal display monitor. They chose from standardised triage responses including an assessment of the nature of the lesion (benign, malignant or unclear), ≥ 1 possible diagnoses, the priority given (high, within 2 weeks; medium, within 4 weeks or low, within 8-12 weeks), suggested management (none, medical therapy, destructive therapy or surgery) and, finally, a dermoscopic description</p>
Target condition and reference standard(s)	<p>Histological plus expert diagnosis</p> <p>Histology: 551</p> <p>Details: All MMs and SCCs (keratoacanthomas were classified as SCCs) were confirmed histopathologically. Final diagnosis confirmed histopathologically in 292 TD referrals (36%) and 259 paper referrals (35%)</p> <p>Expert diagnosis (FTF diagnosis at dermatology clinic): 265</p> <p>Method of diagnosis: dermatologists used dermoscopy to evaluate the study lesions and carried out full body skin examination</p> <p>Prior test data: all relevant clinical information (FTF visits were not blinded to the results of the teledermoscopists)</p> <p>Diagnostic threshold: NR</p> <p>Diagnosis based on: single</p> <p>Number of examiners: NR</p> <p>Observer qualifications: dermatologists (specialists in dermoscopy)</p> <p>Experience in practice: high</p> <p>Experience with index test: high</p> <p>Target condition (final diagnoses)</p> <p>Malignant: MM: 19 (2.3%); MiS: 16 (2.0%); SCC: 17 (2.1%); SCC in situ: 7 (0.9%); BCC: 109 (13.4%); AK: 61 (7.5%); other malignant: 0</p> <p>Benign: dysplastic nevi: 89 (10.9%); BN: 236 (28.9%); SK: 125 (15.3%); other benign: 137 (16.8%)</p>
Flow and timing	<ul style="list-style-type: none"> Excluded participants: none reported Time interval to reference test: all participants were called to attend an FTF visit at the corresponding department of dermatology. A suspicion of MM or SCC was triaged within 2 weeks. After the triage process, all participants were managed according to standard protocols at the hospitals independently of the referral method.

Congalton 2015

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: 1 April 2012 to 31 March 2013 Country: New Zealand
Patient characteristics and setting	Inclusion criteria: people referred from primary care with skin lesions suspicious for melanoma triaged via a VLC instead of being seen FTF at a hospital clinic. Referrals that indicated 1-6 lesions of concern were included Setting: secondary (general dermatology) and private care Prior testing: clinical or dermoscopic (or both) suspicion Setting for prior testing: primary Exclusion criteria: difficult to diagnose lesions - location/site of lesion skin lesions on scalp and genitals were generally excluded, as were those where body site was not clearly identified in the referral Sample size (participants): number eligible: 345; number included: 310 Sample size (lesions): number included: 613 Participant characteristics: Age: median: 58 (range: 15-92) years Gender: male: 142; female 168 Race/ethnicity (%): white: 242 (78%); black or African American: 12 (4%); Hispanic or Latino: 3 (< 1%); Asian: 16 (5%); other: Maori 16 (5%), Pacific islanders 12 (3%); missing: 12 (4%) Lesion characteristics: NR
Index tests	TD Acquisition and transmission of images: participants attended 2 imaging clinics run by a private TD company (MoleMap NZ). Total body photography not offered. Macroscopic and dermoscopic images captured using a Canon G6 camera or MoleCam; regional anatomic views captured using Nikon D3100. Information on the referred lesions such as whether the person had noticed any changes in size, colour, bleeding and itching was recorded. Hair and eye colour, skin type, previous history of sun exposure and family/personal history of skin cancers were also captured. Files were

	archived using proprietary software (MoleMap NZ) and uploaded to a secure server via a virtual private network Nature of images used: clinical and dermoscopic images Any additional participant information provided: participant details Diagnosis based on: single observer Number of examiners: 2 Observer qualifications (remote diagnosis): dermatologist Method of diagnosis: using the MoleMapDiagnose software, 2 experienced dermatologists reviewed participant details and images remotely, making a diagnosis and suggesting management Management options (<i>diagnostic threshold</i>): options included: “(i) specialist assessment or excision of the lesion; (ii) re-imaging in 3-months’ time to detect change (e.g., atypical naevus without criteria for immediate excision); (iii) discharge to care of general practitioner (GP) e.g., for cryotherapy or topical therapy; (iv) self-monitoring and (v) lesion of no concern.”		
Target condition and reference standard(s)	Reference standard - histology alone; 129 lesions excised; 123 considered suspicious for malignancy on TD, 5 considered benign and 1 ‘undiagnosable’ Target condition (final diagnoses as per expert clinical diagnosis and histology) <ul style="list-style-type: none">● Melanoma (in situ and invasive, or NR): 48● Other malignant: NMSC 45● ‘Benign’ diagnoses: 32		
Flow and timing	<ul style="list-style-type: none">● Excluded participants: 1 participant excluded from further analysis because he attended the VLC after the referred lesion had been excised; further 484 lesions assessed at the VLC but, with no final diagnoses reported, could not be included.● Time interval to reference test: medical photographs were taken immediately prior to FTF consultation.

Coras 2003

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: 16-month period. Did not say the date Country: Germany
Patient characteristics and setting	Inclusion criteria: PSLs undergoing excision due to diagnosis of melanoma or atypical nevus, to rule out melanoma or at the participant's request Setting: secondary (general dermatology) (teledermoscopy diagnosis); private care FTF diagnosis Prior testing: NR Setting for prior testing: NR Exclusion criteria: none reported Sample size (participants): NR Sample size (lesions): number eligible: 90; number included: 45 Participant characteristics: none reported Lesion characteristics: none reported
Index tests	In-person assessment (for those comparing FTF vs histology) Method of diagnosis: participating dermatologists with experience in dermoscopy established a clinical diagnosis based on pattern analysis after personal consultation with the participant in their private practice clinics Prior test data: NR Diagnostic threshold: NR Diagnosis based on: single

	Number of examiners: 3 Observer qualifications: dermatologist (experts with great experience in dermoscopy) Experience in practice: high Experience with index test: high TD Acquisition and transmission of images: each of the participating dermatologists acquired digital images after FTF consultation using the same technical equipment (Dermogenius ultra - hand-held CCD camera with pixel size 512×512), and sent them via an email attachment with corresponding participant data and medical history Nature of images used: clinical photographs and dermoscopic images Any additional participant information provided: clinical examination or case notes (or both) Observer qualifications (remote diagnosis): physician experienced in dermoscopy Diagnosis based on: single observer Method of diagnosis: a physician evaluated the images and made a diagnosis based on the images and history of the participant Other detail: the participating dermatologists used the same technical equipment for the acquisition of digital images		
Target condition and reference standard(s)	Reference standard: histology Details: the histological diagnosis of majority of cases was performed at the Department of Dermatology Regensburg Target condition (final diagnoses) <ul style="list-style-type: none">• Melanoma (in situ and invasive, or NR): 16• 'Benign' diagnoses: 29		
Flow and timing	<ul style="list-style-type: none">• Excluded participants: they reported that many images were of poor quality (10) and that only 45 biopsies were done 50 people who did not have histology excluded• Time interval to reference test: unclear• Time interval between index test(s): most likely days (email transmission of images for remote assessment)		
Comparative	Each of the participating dermatologists who conducted a FTF clinical diagnosis acquired digital images of the lesion, and send them via an email attachment with corresponding participant data and medical history		
Notes	-		
Methodological quality			
Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Unclear		
Was a case-control design avoided?	Yes		

Did the study avoid inappropriate exclusions?	Unclear		
Are the included patients and chosen study setting appropriate?	No		
Did the study avoid including participants with multiple lesions?	Unclear		
		Unclear	High
DOMAIN 2: Index Test Teledermatology			
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes		
If a threshold was used, was it pre-specified?	Yes		
Was the test applied and interpreted in a clinically applicable manner?	No		
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Unclear		
Was the test interpretation carried out by an experienced examiner?	Yes		
		Low	High
DOMAIN 2: Index Test FTF diagnosis			
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes		
If a threshold was used, was it pre-specified?	Yes		

Was the test applied and interpreted in a clinically applicable manner?	Yes		
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Yes		
Was the test interpretation carried out by an experienced examiner?	Yes		
		Low	Low
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly classify the target condition?	Yes		
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear		
For studies comparing TD/FTF clinical diagnosis to histology, was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear		
For studies comparing TD to FTF diagnosis, was the clinical diagnosis carried out by an experienced observer?			
		Low	Unclear
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Unclear		
Did all patients receive the same reference standard?	Yes		

Coras 2003 (Continued)

Were all patients included in the analysis?	No		
If the reference standard includes clinical FU of borderline/benign appearing lesions, was there a minimum FU following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?			
		High	
DOMAIN 5: Comparative			
Was each index test result interpreted without knowledge of the results of other index tests or testing strategies?	Unclear		
Was the interval between application of the index tests less than 1 month?	Unclear		
Were all tests applied and interpreted in a clinically applicable manner?	Yes		
		Unclear	Low

Ferrara 2004

Study characteristics	
Patient sampling	Study design: case control Data collection: retrospective image selection/prospective interpretation Period of data collection: NR Country: NR; likely Italy
Patient characteristics and setting	Inclusion criteria: pigmented melanocytic lesions with dermoscopic images (a single image per case) and accompanying histological material were retrieved; approach to lesion selection was not described Setting: unspecified Prior testing: clinical or dermatoscopic (or both) suspicion Setting for prior testing: NR Exclusion criteria: none reported Sample size (participants): NR

	Sample size (lesions): number included: 12 Participant characteristics: 10 males and 2 females, aged 14-79 (median 41) years. Lesion characteristics: 7 lesions removed from the trunk, 4 from the limbs and 1 from the face. Lesions ranged in size from 4 mm to 14 mm in diameter (median 6 mm)		
Index tests	TD Acquisition and transmission of images: dermoscopic images were either acquired on film (Dermaphot) and then digitised (8) or were acquired directly from a digital camera (4); (MoleMax or Videocap) photographic images were also available in 9/12 cases Nature of images used: dermoscopic images Any additional participant information provided: clinical examination or case notes (or both) Observer qualifications (remote diagnosis): dermatologist Diagnosis based on: single observer Number of examiners: 3 Method of diagnosis: stored images were viewed on a standard-resolution colour monitor by 3 remote consultants in a single session; the teledermoscopy diagnosis (melanoma or other lesion type) was recorded by a single consultant, followed by a teledermatopathology diagnosis (based on histological image). The original histological diagnosis from the consultation file was then presented (apparently along with the original clinical diagnosis). “Dermoscopic-pathological remarks” were made and finally a consensus diagnosis was reached by 2 consultants; the latter was taken as the ‘gold standard’ for the study		
Target condition and reference standard(s)	Reference standard: histological diagnosis alone Details: 12 cases with dermoscopic images (1 image per case) and accompanying histological material were retrieved from consultation files. The conventional histopathology diagnosis was regarded as the gold standard: a consensus diagnosis between 2 consultants was requested in order to minimise any influence of the previous dermatopathology diagnosis Target condition (final diagnoses) Melanoma (in situ and invasive, or NR): 7. Invasive melanoma: 4; MiS: 3 ‘Benign’ diagnoses: 5. Junctional nevus: 1; Reed naevus: 1; blue naevus: 1; actinic lentigo: 1; SN: 1		
Flow and timing	<ul style="list-style-type: none">● Excluded participants: NR● Time interval to reference test: images taken at time of FTF consultation; interval to excision NR● Time interval between index test(s): NR

Jolliffe 2001a

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: NR Country: UK
Patient characteristics and setting	Inclusion criteria: people referred by their GP for dermatological assessment of a pigmented lesion at the PLC Setting: specialist unit (skin cancer/pigmented lesions clinic) Prior testing: not explicitly mention but most likely clinical examination Setting for prior testing: primary Sample size (participants): number eligible: 138; number included: 138 Sample size (lesions): number eligible: 144; number included: 144; clinical diagnosis 140; teledermoscopy Participant characteristics: Age: range 15-94 years Gender: male: 48 (34%); female 90 (66%) Lesion characteristics: NR
Index tests	In-person FTF clinical assessment Method of diagnosis: at the PLC a clinical diagnosis (\pm the use of dermoscopy) based upon information in the referral letter and examination findings was made and recorded by the examining doctor Prior test data: clinical examination or case notes (or both) Diagnostic threshold: NR Diagnosis based on: single Number of examiners: 1 Observer qualifications: dermatologist Experience in practice: unclear Experience with index test: unclear TD Acquisition and transmission of images: the examining doctor using a single chip video camera, obtained an image of the pigmented lesion. The image was then archived using proprietary software and images were transmitted through a Fast Screen Machine 2 video overlay card and viewed on a

	15 inch monitor Nature of images used: clinical Any additional participant information provided: clinical examination or case notes (or both) Observer qualifications (remote diagnosis): dermatologist Diagnosis based on: single observer Number of observers: 1 Method of diagnosis: the anonymous video images and the GP's referral letter were then viewed several months later by the same doctor who performed the in-person assessment and a diagnosis made Management options: NR		
Target condition and reference standard(s)	Reference standard: histological diagnosis alone Lesions had been excised either to confirm or refute clinical suspicion of malignancy or atypia. No participant had a lesion removed on account of the study Target condition (final diagnoses) Malignant: melanoma (in situ and invasive, or NR): 2; Lentigo maligna: 2; BCC: 9 Benign diagnoses: atypical naevus: 5; benign melanocytic naevus: 89; SK: 9; solar lentigo: 7; blue naevus: 4; freckle: 2; SN: 2; dermoid cyst: 2; pyogenic granuloma: 2; congenital naevus: 1; naevus sebaceous: 1; DF: 1; haemangioma: 1; abscess: 1; nodular hidradenoma: 1; non-caseating granuloma: 1; apocrine hidrocystoma: 1; angiokeratoma circumscriptum: 1		
Flow and timing	<ul style="list-style-type: none">Excluded participants: in 4 cases it was impossible to make a diagnosis from the image, due to poor image quality.Time interval to reference test: NRTime interval between index test(s): the same doctor viewed the images several months after examining the participant in clinic.		
Comparative	The anonymous video images and the GP's referral letter were then viewed several months later by the same doctor and a diagnosis made. The same doctor who performed the clinical examination viewed the images. The doctor's potential memory of a lesion may, therefore, be perceived to be a source of bias. In reality, > 800 pigmented lesions had been seen by this doctor between the in-person and video examinations, making memory of a specific lesion less likely

Study characteristics	
Patient sampling	Study design: NR Data collection: prospective Period of data collection: reported “a 3 month period” - no dates mentioned Country: Austria
Patient characteristics and setting	Inclusion criteria: people self-referred or referred by a local doctor for evaluation of a skin tumour. Men or women with benign or malignant (or both) skin tumours of melanocytic or non-melanocytic origin Setting: secondary (general dermatology) Department of Dermatology, Medical University of Graz, Austria Prior testing: clinical suspicion of malignancy without dermatoscopic suspicion; patient request for evaluation/excision physician or self-referral Setting for prior testing: primary; all participants were self-referred or referred by a local doctor Exclusion criteria: none reported Sample size (participants): number eligible: 88; number included: 80/88 Sample size (lesions): number eligible: 113 lesions; number included: they reported 104/113 tumours of 80/88 participants were tele-evaluated. However, adding all in table 1 gives > 113 (there were up to 3 (total 322) clinical and 3 dermoscopic (total 278) images) Participant characteristics: Age: mean: missing; median: 69; range: 3-93 years Gender: male: 41/88 available. Not stated who withdrew; female 47/88 available. Not clear who remained Race/ethnicity (%): missing; not stated, but they were Austrian Lesion characteristics: NR
Index tests	In-person FTF clinical assessment Method of diagnosis: not clear from paper how in-person assessment was conducted but most likely VI of the skin (\pm use of dermoscopy) no algorithm described Prior test data: unclear Diagnostic threshold: unclear Diagnosis based on: single Number of examiners: unclear Observer qualifications: NR Experience in practice: NR Experience with index test: NR TD Acquisition and transmission of images: lesions were selected during the outpatient visit and up to 3 clinical (autofocus mode) and dermoscopic images (macro mode) images were obtained by the clinician using a mobile phone with a built in mega-pixel camera (for clinical photos) (Nokia N73 with a built-in 3.2-megapixel camera; Nokia, Helsinki, Finland) with the addition of a pocket dermoscopy device attached to the camera lens for dermoscopic images (DermLite II PRO HR; 3Gen LLC, Dana Point, CA, USA). Images were stored in JPEG format and saved on a computer USB port. Clinical and dermoscopic datasets of each lesion together with relevant clinical information (age, sex, tumour onset, location and participant history) were separately transmitted via a virtual private network for online consultation Nature of images used: clinical photographs and dermoscopic images Any additional participant information provided: clinical examination or case notes (or both)

	relevant clinical information Observer qualifications (remote diagnosis): dermatologist (board certified with clinical expertise in TD and dermoscopy) Diagnosis based on: single observe Method of diagnosis: a board-certified dermatologist with clinical expertise in TD and dermoscopy reviewed each set of clinical and dermoscopic images separately. The lesions were grouped into 4 diagnostic categories (benign melanocytic, benign non-melanocytic, malignant melanocytic and malignant non-melanocytic skin tumours). The teleconsultant based on this then recorded 1 primary and 1 differential diagnosis		
Target condition and reference standard(s)	Reference standard: histological diagnosis and expert diagnosis Details: histopathology was used as the gold standard in 78/104 (75%), including for 32/58 benign lesions (55%). According to ethical principles and to the standards of routine practice, the clinical and dermoscopic FTF diagnoses were considered adequate in those participants with clinically and dermoscopically benign and non-suspicious lesions (i.e. 44% of benign group), and no biopsy procedure was performed Target condition (final diagnoses) Malignant: melanoma (invasive): 2; melanoma (in situ): 1; BCC: 30; cSCC:10; lentigo maligna: 3 Benign: SK: 6; AK: 17; BD: 1; benign naevus: 15; other: soft tissue tumour: 4; angioma: 4; solar lentigo: 3; virus-induced tumour: 1; trichilemmoma: 0; other: 7		
Flow and timing	<ul style="list-style-type: none">Excluded participants: 3 declined participation. In 33% of cases, no history could be obtained. Clinical and 18 dermoscopic pictures were inadequate, so 104 tumours from 80 participants were included.Time interval to reference test: it does not stateTime interval between index test(s): it reported there was a 1-month delay between clinical and dermoscopic telederm picture evaluation		
Comparative	1-month delay between FTF assessment and clinical and dermoscopic telederm evaluation

Mahendran 2005

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: no dates, but over 18 months Country: UK
Patient characteristics and setting	Inclusion criteria: people with a suspicious skin lesion seen by their local GP, had a lesion worthy of dermatologist assessment, willing to have photographic images taken of lesion, willing to see a dermatologist outpatient Setting: primary where participants were recruited; secondary (general dermatology): where final diagnosis was made Prior testing: clinical suspicion of malignancy without dermatoscopic suspicion Setting for prior testing: primary Exclusion criteria: 15% poor-quality index test image Sample size (participants): number included: unclear Sample size (lesions): number included: 106 Participant characteristics: none reported

Lesion characteristics: NR			
Index tests	TD Acquisition and transmission of images: GPs took images of suspicious skin lesions using a digital camera (Nikon Coolpix 950 digital camera (1200 × 1600 pixel resolution), the photograph together with all the relevant history and details about the skin lesion were sent via email to the dermatology department Nature of images used: clinical photographs Any additional participant information provided: past history; dermatographics, site of lesion Observer qualifications (remote diagnosis): dermatologist (consultant dermatologists) Diagnosis based on: single observer (diagnosis made by 1 of 2 consultants) Method of diagnosis: the remote observer gave a diagnosis or differential diagnosis plus a hypothetical management plan where possible Management options: management options included reassuring the participant, minor operation, no action but further review appointment required		
Target condition and reference standard(s)	Reference standard: expert diagnosis (FTF diagnosis at dermatology clinic) Details: all participants were subsequently seen in dermatology outpatient clinic by 1 of the same 2 consultants within 2 weeks and the clinical diagnosis and actual management plan were recorded; lesions also seen FTF by a trainee dermatologist (specialist registrar year 3) 'blinded' to the consultants' reports but the 2×2 data appeared to be for the consultant FTF assessment Target condition (final diagnoses) Malignant: melanoma (invasive): 4; BCC: 37; cSCC 4 Benign diagnoses: AK: 10; BD: 7; lentigo maligna: 1; atypical dysplastic nevi: 6; SK: 27; BN: 20; other: DF: 11; inflammatory dermatoses: 8; haemangioma: 3; scar: 3; viral wart: 3; cellular naevus: 2; chondrodermatitis nodularis helices: 2; congenital naevus: 2; dilated pore of Winer: 2; lesion resolved: 2; squamous papilloma: 2; blue naevus: 1; halo naevus: 1; lichenoid keratosis: 1; myxoid cyst: 1; pressure sore: 1; pyogenic granuloma: 1; sebaceous gland hyperplasia: 1		
Flow and timing	<ul style="list-style-type: none">Excluded participants: 57 'excluded' as could not be managed by TD and no FTF decision given; either insufficient quality for assessment (24) or need to see in clinic to make a decisionTime interval to reference test: within 2 weeksTime interval between index test(s): not stated

Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Yes		
Was a case-control design avoided?	Yes		

Did the study avoid inappropriate exclusions?	Yes		
Are the included patients and chosen study setting appropriate?	Yes		
Did the study avoid including participants with multiple lesions?	Unclear		
		Low	Unclear
DOMAIN 2: Index Test Teledermatology			
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes		
If a threshold was used, was it pre-specified?	Yes		
Was the test applied and interpreted in a clinically applicable manner?	Yes		
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Unclear		
Was the test interpretation carried out by an experienced examiner?	Yes		
		Low	Unclear
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly classify the target condition?	No		
Were the reference standard results interpreted without knowledge of the results of the index tests?	No		

Mahendran 2005 (Continued)

For studies comparing TD/FTF clinical diagnosis to histology, was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Yes		
For studies comparing TD to FTF diagnosis, was the clinical diagnosis carried out by an experienced observer?	Yes		
		High	Low
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		
Did all patients receive the same reference standard?	Yes		
Were all patients included in the analysis?	No		
If the reference standard includes clinical FU of borderline/benign appearing lesions, was there a minimum FU following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	Yes		
		High	

Manahan 2015

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: NR Country: Australia

Patient characteristics and setting	<p>Inclusion criteria: participants aged 50-64 years at high risk of melanoma (fair skin type, previous skin excisions, personal or family history) recruited via the 'QSkin' study (500/43,794 participants were mailed an invitation to participate; plus 59 volunteers who requested participation after learning about the study via university websites or in the local news. Only those with a suitable smartphone could participate. Participants instructed to submit "photos of moles or spots that they 'did not like the look of'," and were given instructions about how to select lesions based on asymmetry and colour</p> <p>Setting: community</p> <p>Prior testing: none</p> <p>Setting for prior testing: N/A</p> <p>Exclusion criteria: no smartphone</p> <p>Sample size (participants): 500 (invited) plus 58 volunteers; of the 230 who completed the questionnaire, the first 58 who expressed interest and had a suitable smartphone were enrolled. 50 attended for FTF skin examination, 1 of whom was later excluded</p> <p>Sample size (lesions): 341 lesions included; 309 with a primary TD diagnosis</p> <p>Participant characteristics:</p> <p>Age: 50-64 years</p> <p>Gender: 49% male</p> <p>Other: 31% with first-degree family member with melanoma and 90% self-reported a fair skin type</p> <p>Lesion characteristics: back: 106 (34%); chest/abdomen: 57 (18%); legs: 56 (18%); arms: 46 (15%); head/neck: 44 (14%)</p>
Index tests	<p>TD</p> <p>Acquisition and transmission of images: study primarily aimed to evaluate skin self-examination (participants randomised to receive 10-step guide to skin self-examination) and mobile TD. All participants used Handyscope FotoFinder dermoscope smartphone attachment (FotoFinder Systems GmbH, Bad Birnbach, Germany) and Handyscope app, to obtain and send magnified lesion image along with a second clinical (macro) image to verify the anatomical site of each skin lesion</p> <p>Nature of images used: clinical and dermoscopic</p> <p>Any additional participant information provided:</p> <p>Diagnosis based on: single observer</p> <p>Number of examiners: 1</p> <p>Observer qualifications (remote diagnosis): board-certified dermatologist, experienced in TD</p> <p>Method of diagnosis: unclear; method of viewing images NR. Dermatologist indicated whether the photograph was suitable to provide a diagnosis before making management recommendation</p> <p>Management options: primary diagnosis, with up to 2 differential diagnoses (cannot extract 2x2), and whether clinical skin examination (FTF) was required (action)</p>
Target condition and reference standard(s)	<p>Reference standard: FTF expert diagnosis (referral accuracy)</p> <p>Details: clinical skin examination performed by a dermatology registrar under supervision of the dermatologist who undertook the telediagnosis. The same management options were recommended in the FTF consultation</p> <p>Target condition (clinical diagnoses FTF)</p> <p>Malignant: BCC: 13; SCC/IEC: 1</p> <p>Benign: atypical naevus: 4; benign naevus: 165; solar lentigo: 22; SK: 81. Non-pigmented: AK: 34; DF: 2; other: 18</p> <p>Recommendation to see FTF (reference standard): 35</p>

Flow and timing	Excluded participants: 8/58 participants did not attend for FTF examination; 1/58 without age restriction; 32/341 lesions did not appear to have a primary TD diagnosis Time interval to reference test: NR Time interval between index test(s): N/A

Massone 2014

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: February 2008 to February 2010 Country: Austria
Patient characteristics and setting	Inclusion criteria: people undergoing health screening for a health insurance company at 3 preventive healthcare centres in Austria selected by GP for second-opinion teleconsulting as part of a preventive medical screening programme Setting: private care Prior testing: clinical or dermatoscopic suspicion (or both) Setting for prior testing: private care Exclusion criteria: poor-quality index test image Sample size (participants): number eligible: 112; number included: 30 Sample size (lesions): number eligible: 121; number included: 32 Participant characteristics: Age: mean: 47; median: 47; range: 18-84 years Gender: male: NR for the number of participants for whom data were presented only given the overall number from eligible participants (642; 93%). Female: NR for the number of participants for whom data were presented only given the overall number from eligible participants (48; 7%) Lesion characteristics: NR
Index tests	TD Acquisition and transmission of images: GPs screened patients and if they noted a suspicious skin lesion then they acquired dermoscopic and if needed photographic images of the same skin lesion. Photographic images were taken using a digital camera, with the addition of a polarised light contact dermatoscope for the dermoscopic images (Canon Powershot digital camera (Canon Inc. , Tokyo, Japan) and DermLite Photo; 3Gen LLC, San Juan Capistrano, CA, USA) adjusted from MoleMax System (Derma Medical Systems, Vienna, Austria)). Images correlated by only age, sex and location of the lesion were transmitted via a virtual private network for teleconsultation. No personal participants' data were transmitted Nature of images used: clinical photographs and dermoscopic images Any additional participant information provided: age, sex and location of the lesion Diagnosis based on: single observer

	Number of examiners: 2 Observer qualifications (remote diagnosis): dermatologist (with high experience of dermoscopy) Method of diagnosis: 1 of 2 dermatologists reviewed the images within 48 hours. First, they reviewed the quality of images on a 3-point scale, ranging from excellent (1) to low quality (3). Second, they assessed the lesion and grouped them into 1 of 4 groups: (1) benign melanocytic, (2) malignant melanocytic, (3) benign non-melanocytic and (4) malignant NMLs and defined them according to WHO guidelines Management options: they also recorded management of the participant as follows, “(i) no further treatment or FU in 3, 6 or 12 months interval in case of benign skin lesions, (ii) referral to a local dermatologist for FTF examination in case of suspicious skin lesions and (iii) excision in case of suspected malignancy.”		
Target condition and reference standard(s)	Reference standard: histological diagnosis plus FTF diagnosis/expert opinion Details: people visiting the healthcare centres were coming from different towns of Austria therefore no institutions were specifically recommended but the patients were free to select a dermatologist of their choice for further assessment. No feedback was requested, it was possible to collect FU data only for the participants referred to the department or who responded to a phone call or a letter. Of these cases, only 19 had histology and 13 had an FTF expert assessment <i>Histology (not further described):</i> number participants/lesions: 19; disease positive: 7; disease negative: 12 <i>Expert opinion:</i> number participants: 13; disease positive: 0; disease negative: 13 Target condition (final diagnoses) Malignant: melanoma: 2, BCC: 5 Benign: dysplastic nevi: 11, SK: 4; other: angioma: porokeratosis: 1; AK: 1		
Flow and timing	<ul style="list-style-type: none">Excluded participants: it was possible to collect FU data only for the participants referred to the department or who responded to a phone call or a letter. 112 participants were eligible as attending the department of dermatology but of these 82 participants were lost to FUTime interval to reference test: NRTime interval between index test(s): NR

Moreno Ramirez 2005

Study characteristics	
Patient sampling	Study design: case series Data collection: retrospective Period of data collection: January to April 2004 Country: Spain
Patient characteristics and setting	Inclusion criteria: people with pigmented, circumscribed lesions fulfilling ≥ 1 of the following criteria: changing lesion ('ABCD changes'), recent lesion (< 3-year history), multiple lesions (> 20 MN counted by the GP), symptomatic lesion (pain, itching, bleeding) or concerned about moles. Accuracy data reported only for those subsequently referred to the PLC and for whom pathology results were available Setting: specialist unit (skin cancer/pigmented lesions clinic)

	<p>Prior testing: most likely clinical examination (the reasons for teleconsultation were listed as concern about moles; recent pigmented lesion; changing lesions; symptoms; multiple lesions)</p> <p>Setting for prior testing: unspecified</p> <p>Exclusion criteria: Excluded difficult to diagnose</p> <p>Sample size (participants): number eligible: 219; number included: 108 referred to PLC, 57 participants included in the final analysis</p> <p>Participant characteristics:</p> <p>Age: mean: 43; range: 2-84 years</p> <p>Gender: male: 77 (35%); female 142 (65%)</p> <p>Lesion characteristics: NR</p>
Index tests	<p>TD</p> <p>Acquisition and transmission of images: 2 digital pictures were taken by the GP using a digital camera at a resolution of 1600×1200 pixels (Coolpix 4300, Nikon). A panoramic view of the lesion area and a close up of the lesion were taken. Images were inserted into a word document with relevant clinical information. This was transmitted via the intranet to an email account at the PLC</p> <p>Nature of images used: clinical photographs</p> <p>Any additional participant information provided: clinical examination or case notes (or both)</p> <p>Diagnosis based on: unclear how many remote observers</p> <p>Number of examiners: NR</p> <p>Observer qualifications (remote diagnosis): dermatologist</p> <p>Method of diagnosis: at the teleconsultation, observers classified the lesions as being, “benign melanocytic naevus, multiple MN (>20 naevi as seen on teleconsultation), atypical naevus, congenital naevus, blue naevus, solar lentigo, lentigo maligna, melanoma, special melanocytic lesion (genital naevus, acral naevus, recurrent naevus), seborrhoeic keratoses, basal cell carcinoma (BCC), DF, vascular lesion, non-pigmented lesion, or a ‘difficult to diagnose’ lesion.” After evaluation of the pictures and clinical information, a report was returned to the GP at the primary care centre, with suggestions regarding the diagnosis and management of the case</p> <p>Management options: limited to ‘referral’ or ‘non-referral’ of the participant to the FTF clinic. Participants who had readily identifiable benign lesions such as benign melanocytic naevus, solar lentigo, SK, DF, vascular lesions and non-pigmented lesions were not referred to the PLC. All other remaining categories were routinely referred to the PLC for FTF assessment</p>
Target condition and reference standard(s)	<p>Reference standard: histological diagnosis</p> <p>Details: at the PLC, physical and dermoscopic examinations were carried out, as well as excisional biopsy in suspicious or malignant cases, and FU of participants with risk factors for melanoma (16/25 benign underwent histology)</p> <p>Target condition (final diagnoses)</p> <p>Melanoma (in situ): 1, BCC: 23; lentigo maligna: 3; dysplastic nevi: 16, common: nevi 8; blue nevi: 4</p>
Flow and timing	<ul style="list-style-type: none"> Excluded participants: 13 difficult to diagnosis cases, plus 28 with ‘malignant or suspicious lesions’ were excluded from 2x2 tables Time interval to reference test: unclear - only mentioned, “Teleconsultation reports were sent to the GP in a mean time of 44 h [hours] (range 2-96 h). Patients referred to the face-to-face clinic were seen within the following two weeks (mean of 8 days, range 5-14). Dermatologists at the PLC spent an average of 2.3 h per week in evaluating the teleconsultations received.” Time interval between index test(s): N/A

Phillips 1998

Study characteristics	
Patient sampling	Study design: case series Data collection: NR but appeared prospective Period of data collection: 1996 Country: USA
Patient characteristics and setting	Inclusion criteria: participants attending 4 skin cancer screenings at community hospitals in rural eastern North Carolina, USA Setting: community Prior testing: none Setting for prior testing: N/A Exclusion criteria: none reported Sample size (participants): 51 Sample size (lesions): 107 Participant characteristics: Age: mean: 46.7 years Gender: male: 8 (15.7%) Lesion characteristics: NR
Index tests	TD Acquisition and transmission of images: all sites were on a 1/2 T-1 link (786 kbs). All sites had 3 cameras available, each of which was used in evaluating the participants: a full-body camera, a lens for viewing the lesions close up, and a magnifying lens that allowed even closer views as well as examination with polarised light (CLI CODEC (Panasonic 3-chip or Canon 1-chip)). All monitors offered 620 lines of resolution. It was not clear who operated the cameras during the teleconsultations. The in-person evaluation was conducted first so that if a complete skin examination was performed, representative lesions were selected by the on-site physician for evaluation by the remote physician Nature of images used: live link Any additional participant information provided: physicians could communicate directly with the participant Diagnosis based on: single observer Number of examiners: 2; each examiner was the on-site physician at 2 screenings and the "remote physician" at 2 screenings

	Observer qualifications (remote diagnosis): dermatologist Method of diagnosis: live link consultation; physicians could communicate directly with the study participant Management options: most likely diagnosis for a given lesion; the degree of concern that a specific lesion was malignant; and recommendation as to whether to do a biopsy of the lesion		
Target condition and reference standard(s)	Reference standard: expert diagnosis (referral accuracy) Details: all participants were first evaluated by the on-site physician. Participants were given a choice of having a total body examination, only the sun-exposed skin, or a specific lesion(s) evaluated by the on-site physician. This physician recorded specific lesions on an image of the human body and the most likely diagnosis for a given lesion; the degree of concern that a specific lesion was malignant; and recommendation as to whether to do a biopsy of the lesion. If a complete skin examination was performed, representative lesions were selected by the on-site physician for evaluation by the remote physician. The participant was subsequently seen by the remote dermatologist, and the same data were recorded Target condition (FTF diagnoses) Malignant: BCC: 2; SCC: 3; lentigo maligna: 1 Benign: SK: 27; BN: 32; AK: 14; lentigo: 10; other: 30

Shapiro 2004

Study characteristics	
Patient sampling	Study design: case series Data collection: prospective Period of data collection: 10 July 1998 to 4 August 2000 Country: USA
Patient characteristics and setting	Inclusion criteria: PCP referred only those people with skin growths that posed a true diagnostic challenge Setting: primary, recruitment of study participants from PCP (estimated 50% of PCP participants had dermatological lesions that were encountered during routine evaluation and 3% present exclusively for dermatological reasons). Private (FTF consultation with the local dermatologist in private practice). Secondary care (images sent from PCP to academic dermatologist for SAF dermatological consultation) Prior testing: a network community PCP-recruited participants whom he judged to require dermatological consultation for evaluation of a cutaneous growth Setting for prior testing: primary Exclusion criteria: people who underwent previous evaluation by a dermatologist Sample size (participants): number eligible: 61; number included: 49 Sample size (lesions): NR Participant characteristics: NR Lesion characteristics: NR
Index tests	TD Acquisition and transmission of images: images were acquired by the PCP using an Olympus D-600L digital camera. The first image captured the head and upper trunk. This was followed by an image of the affected body part. The image and a clinical history were downloaded to a personal computer using a serial port interface and accompanying software. The image transmission was performed via e-mail using HUPNet, a private encrypted University of Pennsylvania Health System area network Nature of images used: clinical photographs Any additional participant information provided: clinical history Observer qualifications (remote diagnosis): dermatologist (1) (academic dermatologist with over 20 years' experience in clinical dermatology) Diagnosis based on: single observer

	Number of observers: 1 Method of diagnosis: the images were reviewed by the PCP immediately before they were sent to a board certified academic dermatologist for teledermatological consultation. After assessing the case, the teledermatologist notified the PCP of the diagnosis or differential diagnosis and indicate on a standard data collection sheet whether a sampling biopsy was necessary. The reason for recommending biopsy was specified as well Management options: asked to choose a management plan from 15 entries including 3 biopsy plans (to rule out malignancy, to establish a diagnosis or to remove a benign lesion for cosmetic purposes)		
Target condition and reference standard(s)	FTF diagnosis as reference standard Method of diagnosis: the participants were simultaneously scheduled for an FTF visit with the local dermatologist, who is in private practice, within 1 month. The FTF dermatologist completed a standardised consultation form notifying the PCP of his decision regarding the diagnosis, differential diagnosis and whether a biopsy was indicated. A biopsy was performed at that visit by the FTF dermatologist if the FTF dermatologist or the SAF teledermatologist favoured biopsy of the lesion Prior test data: the telediagnosis triage decision was contained in a sealed envelope which was opened by the FTF dermatologist after making his decision. Biopsy was then carried out by the FTF dermatologists if recommended by either dermatologist Diagnostic threshold: not described Diagnosis based on: single Number of examiners: 1 Observer qualifications: dermatologist Experience in practice: > 20 years of experience in clinical dermatology Experience with index test: high Target condition (for 26 lesions undergoing biopsy; 23 on dermatologist recommendation and 3 at participant request) Malignant: BCC: 5; cSCC: 4 Benign: benign neoplasms: 17 Assumed benign (no biopsy): 23 (including 1 participant who refused biopsy)		
Flow and timing	<ul style="list-style-type: none">Excluded participants: 11 breached the study protocol and were not included in the analysis. Of the latter 11, 4 failed to present to the FTF dermatologist, 4 saw a different FTF dermatologist, 1 died of unrelated causes before seeing the FTF dermatologist, and 2 underwent evaluation of different lesions by the SAF teledermatologist and FTF dermatologist.Time interval to reference test: participants were simultaneously scheduled for an FTF visit with the local dermatologist, who was in private practice, within 1 month.Time interval between index test(s): N/A

Wolf 2013

Study characteristics	
Patient sampling	Study design: case control Data collection: retrospective image selection/prospective interpretation Period of data collection: NR Country: USA
Patient characteristics and setting	Inclusion criteria: people with pigmented lesions that were considered atypical in clinical appearance by ≥ 1 dermatologist and for which a clear histological diagnosis had been rendered by a board-certified dermatopathologist. Images selected from image database in following categories: categories: invasive melanoma, MiS, lentigo, benign nevus (including compound, junctional and low-grade dysplastic nevi), DF, SK and haemangioma. Sampling not described Setting: unspecified Prior testing: selected for excision (no further detail) Setting for prior testing: unspecified Exclusion criteria: poor-quality index test image. Images that contained any identifiable features, such as facial features, tattoos or labels with participant information were excluded or cropped to remove the identifiable features or information. Lesions with equivocal diagnoses, such as “melanoma cannot be ruled out” or “atypical melanocytic proliferation,” were excluded, as were SN, pigmented spindle cell nevus of Reed, other uncommon or equivocal lesions, and lesions with moderate- or high-grade atypia Sample size (participants): NR Sample size (lesions): 188 Participant characteristics: NR Lesion characteristics: NR
Index tests	TD Acquisition and transmission of images: the images of skin lesions were selected from a database of images that are captured routinely before skin lesion removal to allow clinicopathological correlation in making medical management decisions. Only used close-up images of lesions and those that contained any identifiable features, such as facial features, tattoos or labels with participant information, were excluded or cropped to remove the identifiable features or information Nature of images used: photographic images Any additional participant information provided: no further information used Method of diagnosis: application run on a smartphone sent each image to a board-certified dermatologist for evaluation, and assessment that was returned to the user within 24 hours. The identity of the dermatologist was not given, and it was unclear whether all the images were read by the same dermatologist or by several different dermatologists. The output given was “atypical,” which was considered to be a positive test result, or “typical,” which was considered to be a negative test result Diagnosis based on: unclear how many observers

	Number of examiners: unclear Observer qualifications (remote diagnosis): board-certified dermatologist Experience in practice: unclear Experience with index test: unclear		
Target condition and reference standard(s)	Reference standard: histological diagnosis alone Details: <i>histology (not further described)</i> Target condition (final diagnoses) Malignant: melanoma (in situ and invasive): 60 Benign: 'benign' diagnoses: 128		
Flow and timing	<ul style="list-style-type: none">Excluded participants: authors reviewed 390 images for possible inclusion in this study. Excluded 202 as being of poor image quality, containing identifiable participant information or features, or lacking sufficient clinical or histological information.Time interval to reference test: N/A		
Comparative			
Notes	-		
Methodological quality			
Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Yes		
Was a case-control design avoided?	No		
Did the study avoid inappropriate exclusions?	No		
Are the included patients and chosen study setting appropriate?	No		
Did the study avoid including participants with multiple lesions?	Unclear		
		High	High
DOMAIN 2: Index Test Teledermatology			
Were the index test results interpreted without knowledge of	Yes		

Wolf 2013 (Continued)

the results of the reference standard?			
If a threshold was used, was it pre-specified?	Yes		
Was the test applied and interpreted in a clinically applicable manner?	No		
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Yes		
Was the test interpretation carried out by an experienced examiner?	Yes		
		Low	High
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly classify the target condition?	Yes		
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear		
For studies comparing TD/FTF clinical diagnosis to histology, was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear		
For studies comparing TD to FTF diagnosis, was the clinical diagnosis carried out by an experienced observer?			
		Low	Unclear
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Unclear		

Did all patients receive the same reference standard?	Yes		
Were all patients included in the analysis?	No		
If the reference standard includes clinical FU of borderline/benign appearing lesions, was there a minimum FU following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?			
		High	

ABCD(E): asymmetry, border, colour, differential structures (enlargement); AK: actinic keratosis; AMN: atypical melanocytic naevi; BCC: basal cell carcinoma; BD: Bowen's disease; BN: benign naevi; cSCC: cutaneous squamous cell carcinoma; DF: dermatofibroma; FTF: face-to-face; FU: follow-up; GP: general practitioner; IEC: intraepithelial carcinoma; MM: malignant melanoma; MiS: melanoma in situ (or lentigo maligna); MN: melanocytic naevi; MPU: Mobile Prevention Unit; N/A: not applicable; NML: non-melanocytic lesion; NMSC: non-melanoma skin cancer; NR: not reported; PCP: primary care provider; PLC: pigmented lesion clinic; PLD: polarised light dermoscopy; PSL: pigmented skin lesion; SAF: safe-and-forward; SCC: squamous cell carcinoma; SK: seborrhoeic keratosis; SN: Spitz nevi; TD: teledermatology; VA: Veteran Affairs; VI: visual inspection; VLC: virtual lesion clinic; WHO: World Health Organization; WPC: within-person comparison (of tests).

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Armstrong 2007	Exclude not a primary study
Baba 2005	Exclude on study population
Badertscher 2015	Exclude on 2x2 data; for VI/Derm - only gave number of correct diagnoses (not broken down by TP/TN) and gives GP 'score' between T0 and T1 Exclude on index test - not a teledermatology study
Barnard 2000	Exclude on target condition; the primary target condition was not relevant to our reviews
Bashshur 2015	Exclude not a primary study; narrative review
Bataille 2011	Exclude conference abstract

(Continued)

Bergmo 2000	Exclude not a primary study
Borve 2013	Exclude on target condition; included 1 melanoma metastases and 1 in situ SCC as D+ (these made up 5% of malignant group); author contacted ("Table 2 provided estimates of the diagnostic accuracy of the face-to-face dermatologist and the two teledermoscopists, however in order to include the results in our review we would need the underlying 2x2 contingency tables for these statistics. Is it at all possible for you to provide us with them for each observer, particularly in regard to the 'Primary diagnosis' and the 'Benign vs malignant'")
Boyce 2011	Exclude on study population; no breakdown given, just 7 suspicious lesions Exclude on reference standard; no data given but only 7 referred on for formal assessment. Definitely < 50% histology rate
Braun 2000	Exclude on 2x2 data Exclude but contacted authors. Sensitivity was reported in Table II but specificity unclear. Study reports % of correct identification of each lesion type rather than FPs and does not provide numbers misclassified as melanoma, or other malignancy. Also possibility of overlap with later publications, e.g. Coras 2003
Brown 2000	Exclude not a primary study
Burgiss 1997	Exclude on reference standard reports actions on telediagnosis (primarily for cost purposes) and did not give final diagnoses (histo) or FTF diagnosis for all lesions
Chen 2002	Exclude on sample size Study was based on individual participant images (< 5 cases). Only 4 lesions in total used in study (1 non-BCC, 1 SK, 1 KA, 1 AK)
D'Elia 2007	Exclude on study population; not focused on suspected skin cancer Exclude on 2x2 data; looked at agreement between diagnoses only
Di Stefani 2007	Exclude on sample size; < 5 malignant: of 7 excised: 1 melanoma (MiS associated with a nevus), 1 pigmented BCC and 5 melanocytic nevi. Both tele-dx recommended the 2 malignancies for excision but no further breakdown of agreement/disagreement given Exclude on 2x2 data 7 'D+' according to FTF decision to excise but only reports kappa values for agreement with tele-dx
Du Moulin 2003	Exclude on study population Exclude on target condition
Edison 2008	Exclude on study population
Eminovic 2009	Exclude, not a primary study Exclude on study population Exclude on target condition
Fabbrocini 2008	Exclude on 2x2 data; there was insufficient data provided for each index test to populate 2x2 table Exclude but contacted authors: "As we can only include DTA studies - do you have a cross tabulation of each clinician's diagnosis (e.g. at threshold of >=3 on 7 point checklist) against the histological diagnosis

(Continued)

	and/or a cross tabulation of the remote diagnosis against the Face to Face diagnoses?"
Ferrandiz 2007	Exclude on study population; all had a strong clinical diagnosis of NMSC or fast-growing tumour, the purpose of the test was primarily to inform treatment plans Exclude on 2x2 data; 4 of the original 134 appeared to have missing histology and did not know what the additional clinical cases of each lesion were classed as on histology, e.g. the 14 extra BCCs and 5 KAs
Ferrandiz 2012	Exclude on target condition; on included CM
Gilmour 1998	Exclude on study population Exclude on target condition
Granlund 2003	Exclude on study population
Griffiths 2010	Exclude on reference standard
Harrison 1998	Exclude on target condition, no breakdown of final diagnoses (histo) or of recommendations from FTF consultation Exclude on sample size; could not determine how many D+ for either reference standard Exclude on 2x2 data; no underlying data provided; diagnostic 'accuracy' of teleconsultation reported as 71% for 210 participants compared to 49% for the referring GPs (49%). Also stated that "telemedicine was able to detect malignancies in 94% of cases compared with only 70% detected by general practitioners."
Heffner 2009	Exclude on target condition
Hicks 2003	Exclude not a primary study
High 2000	Exclude on study population; not all suspected of skin cancer 'dermatological conditions' including dermatitis, acne, verruca, etc Exclude on 2x2 data; reported agreement only; no breakdown of diagnoses/management decisions Exclude on reference standard; table of final diagnoses appeared to be based on FTF diagnoses with histology obtained for 69/106 (65%), so was ineligible for a tele-dx vs histo comparison (diagnostic accuracy) and is not tele-dx vs FTF (referral accuracy) either
Hue 2016	Exclude on reference standard; final diagnoses/FTF decisions given only for 17 recommended for rapid referral on tele-dx; no data for remaining 395 with non-urgent derm referral/annual FU recommendation/discharge Exclude on sample size; for tele-dx vs histo, only 5 excised included 1 melanoma Exclude on 2x2; no data for tele-dx vs FTF
Hwang 2014	Exclude on study population
Ishioka 2009	Exclude on target condition No breakdown of disease positive 'malignant' provided
Kahn 2013	Exclude on target condition
Knol 2006	Exclude on study population

(Continued)

Krupinski 1999	Exclude on 2x2 data; reported only diagnostic concordance/agreement
Lamel 2012	Exclude on 2x2 data; reported only summary concordance in diagnosis and management decisions between decisions based on mobile phone image and in person; insufficient detail to work out referral accuracy Exclude but contacted authors, "Study presents data on diagnostic and management concordance between in person and remote (via mobile phone app) diagnoses, are any diagnostic accuracy data available, e.g. observers diagnosis of malignant lesion when assessed remotely versus FtF diagnosis of malignancy?"
Lamminen 2000	Exclude not a primary study
Leshner 1998	Exclude on study population; included people with 'skin problems' (included wide range of diagnoses) Exclude on sample size; could extract referral accuracy (tele-dx vs FTF) but only 4 lesions with malignant diagnosis on FTF (4 BCCs)
Lewis 1999	Exclude on 2x2 data; study appeared to meet all eligibility criteria but disease prevalence not given alongside sensitivity/specificity Exclude but contacted authors: "(Sensitivity and specificity of remote diagnosis in comparison to FtF diagnosis are provided but we would need number D+ in order to complete 2x2 table)."
Loane 1998a	Exclude on study population
Loane 1998b	Exclude not a primary study
Loane 2000	Exclude on study population; not focused on potentially malignant skin lesions; could not derive any comparative data for detection of 'tumours'
Loane 2001a	Exclude not a primary study
Loane 2001b	Exclude on study population
Lowitt 1998	Exclude on study population
Lyon 1997	Exclude on 2x2 data: for operative referrals, only histo diagnosis given with overall number of disagreements by FTF and tele-dx; no clear breakdown of index test results to derive 2x2 Exclude on study population; not all suspected of skin cancer
Martinez-Garcia 2007	Exclude on 2x2 data; not test accuracy Exclude on reference standard; no reference standard reported; describes only tele-dx
Massone 2007	Exclude on reference standard; did not meet our criteria for diagnostic accuracy reference standard (only 12/25 (48%) of benign group with histo, including 1 AK as benign instead of malignant); and data not presented to allow extraction of referral accuracy (tele-dx vs FTF) (included 955 lesions and reported tele-dx recommendations for all 955; 121 were recommended for excision or for FTF consult but FU data only available for 32 of these (19 with histo dx and 13 with FTF diagnosis)) Exclude on 2x2 data; data not clearly presented to allow extraction of referral accuracy (tele-dx vs FTF alone); could only extract tele-dx vs FTF diagnosis of malignancy if we assume that all 7 malignant lesions were diagnosed as such by FTF; from table 2 we only know that all 7 were excised presumably following FTF consult

(Continued)

May 2008	Exclude on 2x2 data: no data for a 2x2 table Exclude on index test; effect on consultant priority of GP referral with photograph vs referral with no accompanying photograph
McGraw 2009	Exclude on study population
McManus 2008	Exclude on study population
Moreno-Ramirez 2006	Exclude on sample size; comparison is tele-dx vs final diagnosis (58/61 were biopsied); only 1 melanoma and 2 BCC
Moreno-Ramirez 2007	Exclude on reference standard: did not meet either criteria for eligible reference standard. Table 1 cross-tabulates the telediagnosis (refer/not refer) against a gold standard which appeared to be a combination of the FTF diagnosis (for those with clinically and dermoscopically benign and non-suspicious lesions, and with a diagnostic confidence level of 3 after the FTF diagnosis) and histology (those with higher concern at FTF evaluation were excised)
Moreno-Ramirez 2009	Exclude on study population Exclude on reference standard
Ndegwa 2010	Exclude not a primary study; technology report
Nordal 2001	Exclude on study population Exclude on target condition
Oakley 1997	Exclude on study population Exclude on target condition
Oakley 2006	Exclude on 2x2 data; insufficient data presented Exclude but contacted authors, "We are looking to compare telederm dx with FtF diagnosis within a diagnostic accuracy framework (i.e. in a 2x2 contingency table) but in order to include your paper we would need information on the misdiagnoses. Using the FtF diagnosis as the gold standard, we can use the data in Table 2 to derive the 'sensitivity' of the tele-Dx agreement for diagnosis of melanoma, BCC and SCC (%agreement), but we would need to know the % of tele-dx reports that 'misdiagnosed' the other lesion types as malignant in order to derive 'specificity'. Would you be at all able to supply this data? <i>We could use the data in Table 6 to cross-tabulate the management decisions between the two approaches, if we collapse the tele-Dx cat3 and cat4 groups together. However the % agreement for the teledermatology classification adds to greater than 100."</i>
Oztas 2004	Exclude on study population Exclude on target condition
Pak 1999	Exclude not a primary study; review of service
Pak 2002	Exclude conference abstract; no full text paper found
Pak 2003a	Exclude on study population

(Continued)

Pak 2003b	Exclude on study population
Pak 2007	Exclude on reference standard; reference standard not clear
Pak 2009	Exclude not a primary study
Patro 2015	Exclude on target condition
Perednia 1998	Exclude on study population; not all suspected of skin cancer Exclude on index test; not an evaluation of accuracy of teledermatology but of effect of access to telemedicine on GP confidence and referral decisions
Phillips 1997	Exclude on sample size; 68 lesions; FTF diagnosis of 4 skin cancers (tele- and FTF diagnoses concordant for 1 melanoma and 2 BCC; FTF dx of 1 additional SCC in 1 further participant); no final diagnoses (histo) recorded Exclude on 2x2 data; presents agreement between observers only Exclude on study population; not all suspected of skin cancer
Piccolo 1999	Exclude on 2x2 data; reports data for tele-dx, FTF and histo; breakdown of discordant results between tele-dx vs FTF and tele-dx vs histo is given but only gives number (%) concordant; did not give number TP and TN to allow 2x2 to be estimated for either comparison
Piccolo 2002	Exclude not a primary study; review article
Rashid 2003	Exclude on study population
Ribas 2010	Exclude on study population
Romero 2010	Exclude on study population
Romero 2014	Exclude on study population
Seidenari 2004	Exclude on 2x2 data; no data to populate 2x2 table just ROC curve values given Exclude but contacted authors, "TABLE 5 provides AUC values for each diagnosis for both formats and observers; requested data in 2x2 format, e.g. for melanoma 'certain' against final diagnosis and for melanoma 'certain or fairly certain' against final diagnosis?"
Senel 2013	Exclude on 2x2 data; no accuracy data available. For teledermatology it looks like they only gave the % of correct diagnoses (Table 6) per dermatologist but give no breakdown by disease positive/negative so could not work out 2x2 data
Shin 2014	Exclude on target condition
Tait 1999	Exclude on study population; not all suspected of skin cancer 'people with visible skin lesion or lesions' (wide range in diagnoses recorded)

(Continued)

Tan 2010a	Exclude on reference standard; no reference standard described Exclude on 2×2 data; not test accuracy; reported agreement between 5 dermatologists' telediagnosis, not against histology or FTF diagnosis
Tan 2010b	Exclude on 2×2 data; study appeared to meet eligibility criteria; however, although sensitivity and specificity values were provided in Table 4 per dermatologist, it was not possible to work back to the underlying 2×2 (final diagnoses by histopath not given and FTF diagnoses for the same 491 lesions differ in Table 1 according to dermatologist A and dermatologist B)
Tandjung 2015	Exclude on target condition; 'malignant' included: AK, BD, dysplastic nevus, lentigo maligna, SCC, BCC, MM and KA Exclude on index test; GPs sent images for teledermatology opinion; then free to send for biopsy or not; results shown were only for those that were biopsied, according to teledermatology advice
Taylor 2001	Exclude on study population; not all suspected of skin cancer; wide variety of conditions included Exclude on 2×2 data; reported % agreement only
Tucker 2005	Exclude on target condition; no breakdown of either final diagnoses or tele-dx Exclude on 2×2 data; reports agreement only Exclude on study population; not all suspected of skin cancer
van der Heijden 2013	Exclude on 2×2 data; only reported Kappa values for histology vs FTF and histology vs tele-dx (for each of 4 teledermatologists) but no underlying data given
Vano-Galvan 2011	Exclude on study population: not specific to skin cancer, population included infectious disease and inflammatory disease Exclude on 2×2 data; only gives % agreement between tele-dx and FTF (gold standard)
Warshaw 2009a	Exclude on 2×2 data; only reports accuracy Exclude duplicate or related publication; author contacted in regard to 2010 paper Exclude but contact author. Study presented diagnostic accuracy of teledermatology and clinic diagnosis in comparison to histopathology; in order to include in our review, data would need to be presented as a 2×2 contingency table, either per type of malignancy e.g. tele-dx classification of melanoma vs not melanoma against histological diagnosis of melanoma/not melanoma, or with malignant diagnoses grouped together, i.e. tele-dx of malignancy vs not malignant against same histological breakdown. Requested these data for the clinic diagnosis and for each method of telediagnosis for this study and for Warshaw 2009b . **Author provided some data for detection of melanoma only and for use of macro images only for 2010 paper (pigmented and non-pigmented lesion combined)
Warshaw 2009b	Exclude on 2×2 data; only reports accuracy Exclude duplicate or related publication Exclude but contact author. See Warshaw 2009a
Warshaw 2010a	Exclude on 2×2 data; not test accuracy; interobserver agreement for subsample of Warshaw 2009a / Warshaw 2010b trial
Warshaw 2015	Exclude on 2×2 data; only gives agreement between teledermatology diagnosis and FTF diagnosis

(Continued)

Watson 2010	Exclude on target condition
Weingast 2013	Exclude on study population
Weinstock 2002	Exclude not a primary study
Weinstock 2009	Exclude not a primary study
Whited 1999	Exclude on 2x2 data; only gave % agreement between tele-dx and FTF and % correct diagnoses of tele-dx vs histo
Whited 2002	Exclude not a primary study
Whited 2003	Exclude not a primary study
Whited 2004	Exclude not a primary study
Whited 2006	Exclude not a primary study; review article
Whited 2010	Exclude not a primary study
Whited 2016	Exclude not a primary study
Williams 2001	Exclude not a primary study
Williams 2007	Exclude not a primary study
Wootton 2000	Exclude on study population Exclude on target condition
Zelickson 1997	Exclude on study population

AK: actinic keratosis; AUC: area under curve; BCC: basal cell carcinoma; BD: Bowen's disease; CM: cutaneous melanoma; D+: disease positive; Derm: dermoscopy; DTA: Diagnostic Test Accuracy; Dx: diagnosis; FP: false positives; FTF: face-to-face; FU: follow-up; GP: general practitioner; histo: histology; KA: keratoacanthoma; MM: malignant melanoma; MiS: melanoma in situ (or lentigo maligna); NMSC: non-melanoma skin cancer; ROC: receiver operating characteristic; SCC: squamous cell carcinoma; SK: seborrheic keratosis; tele-Dx: teledermatology diagnosis; TP: true positive; TN: true negative; VI: visual inspection.

DATA

Presented below are all the data for all of the tests entered into the review.

Tests. Data tables by test

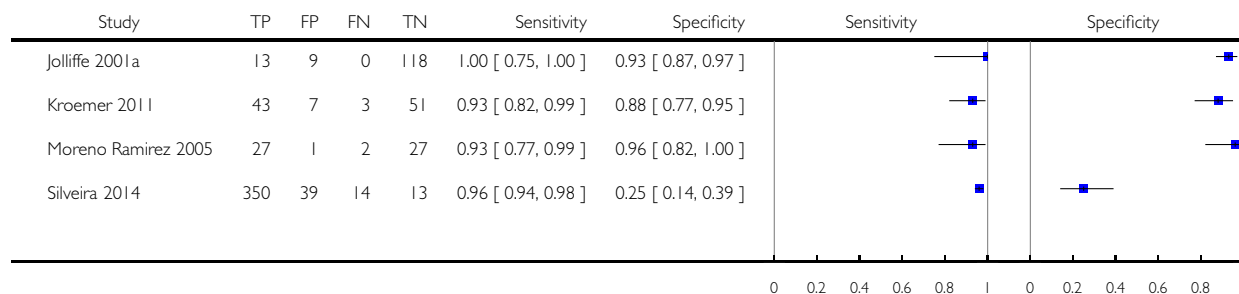

Test	No. of studies	No. of participants
1 Teledermatology - photographic image vs histology (any)	4	717
2 Teledermatology - dermoscopic image vs histology (any)	1	104
3 Teledermatology - photographic + dermoscopic image vs histology (any)	3	871
4 Expert face-to-face (visual inspection (VI) + dermoscopy) vs histology (any)	2	248
5 Teledermatology - photographic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants)	4	1834
6 Teledermatology - dermoscopic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants)	2	116
7 Teledermatology photographic + dermoscopic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants)	4	664
8 Expert face-to-face (VI + dermoscopy) (invasive melanoma or atypical intraepidermal melanocytic variants)	3	1663
9 Teledermatology - photographic + dermoscopic image vs histology (invasive melanoma)	1	43
10 Expert face-to-face (VI + dermoscopy) vs histology (invasive melanoma)	1	43
11 Teledermatology - dermoscopic image vs histology (acral melanoma)	1	77

12 Teledermatology - photographic image vs histology (basal cell carcinoma (BCC))	3	301
13 Teledermatology - dermoscopic image vs histology (BCC)	1	104
14 Teledermatology - photographic + dermoscopic image vs histology (BCC)	1	256
15 Expert face-to-face (VI + dermoscopy) vs histology (BCC)	2	248
16 Teledermatology - photographic image vs histology (cutaneous squamous cell carcinoma (cSCC))	1	104
17 Teledermatology - dermoscopic image vs histology (cSCC)	1	104
18 Expert face-to-face (VI + dermoscopy) vs histology (cSCC)	1	104
19 Teledermatology - photographic image vs face-to-face clinical diagnosis (immediate action)	3	951
20 Teledermatology - photographic image vs face-to-face clinical diagnosis (of malignancy)	1	90
21 Teledermatology - photographic image vs face-to-face clinical diagnosis (immediate action or follow-up)	1	106
22 Teledermatology - photographic image vs face-to-face clinical diagnosis (immediate action; registrar data)	1	796
23 Teledermatology - photographic/dermoscopic image vs face-to-face clinical diagnosis (immediate action)	1	301
24 Teledermatology - live link vs face-to-face clinical diagnosis (diagnosis of any skin cancer)	1	107
25 Teledermatology - live link vs face-to-face clinical diagnosis (definitely/probably malignant)	1	107
26 Teledermatology - live link vs face-to-face clinical diagnosis (biopsy decision)	1	107

Test 1. Teledermatology - photographic image vs histology (any).

Review: Teledermatology for diagnosing skin cancer in adults

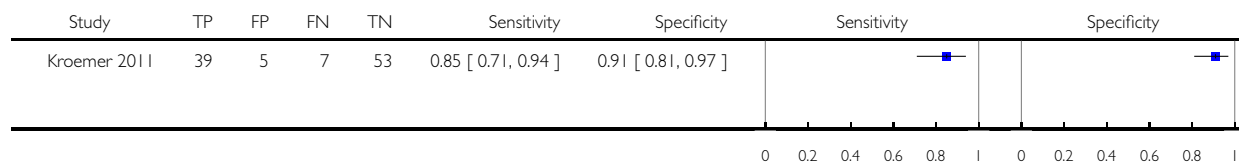

Test: 1 Teledermatology – photographic image vs histology (any)

Test 2. Teledermatology - dermoscopic image vs histology (any).

Review: Teledermatology for diagnosing skin cancer in adults

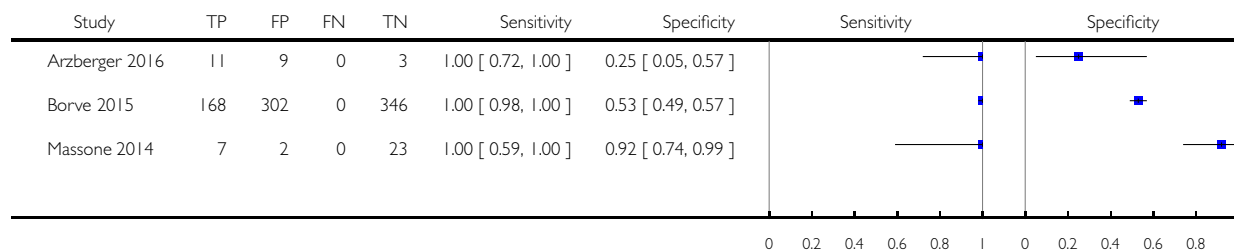

Test: 2 Teledermatology – dermoscopic image vs histology (any)

Test 3. Teledermatology - photographic + dermoscopic image vs histology (any).

Review: Teledermatology for diagnosing skin cancer in adults

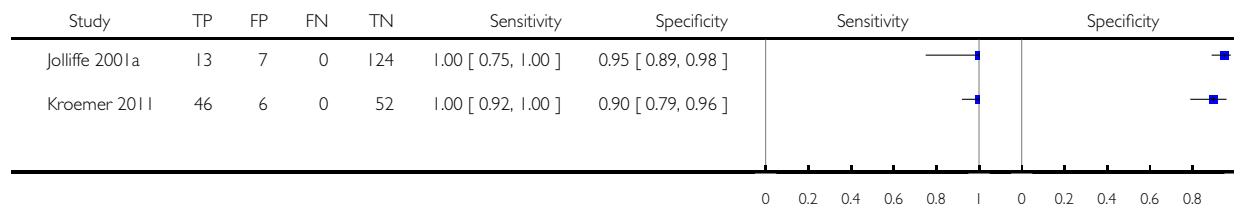

Test: 3 Teledermatology – photographic + dermoscopic image vs histology (any)

Test 4. Expert face-to-face (visual inspection (VI) + dermoscopy) vs histology (any).

Review: Teledermatology for diagnosing skin cancer in adults

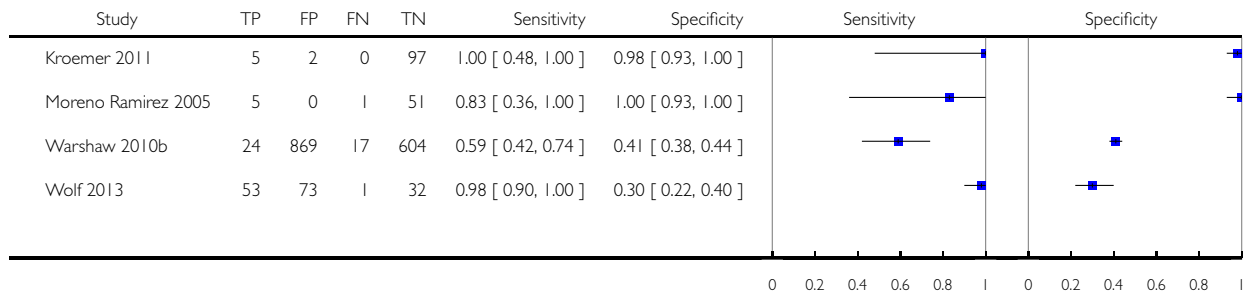

Test: 4 Expert face-to-face (visual inspection (VI) + dermoscopy) vs histology (any)

Test 5. Teledermatology - photographic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants).

Review: Teledermatology for diagnosing skin cancer in adults

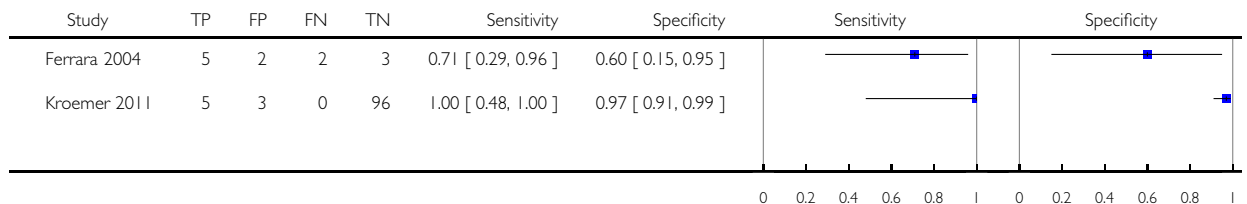

Test: 5 Teledermatology – photographic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants)

Test 6. Teledermatology - dermoscopic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants).

Review: Teledermatology for diagnosing skin cancer in adults

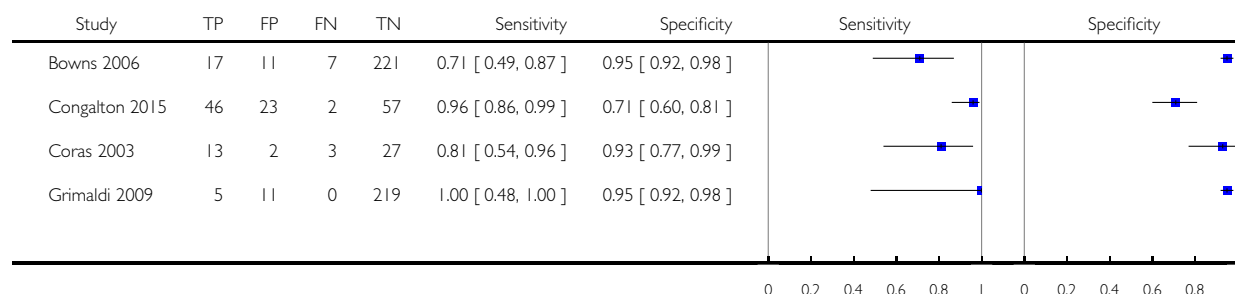

Test: 6 Teledermatology – dermoscopic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants)

Test 7. Teledermatology photographic + dermoscopic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants).

Review: Teledermatology for diagnosing skin cancer in adults

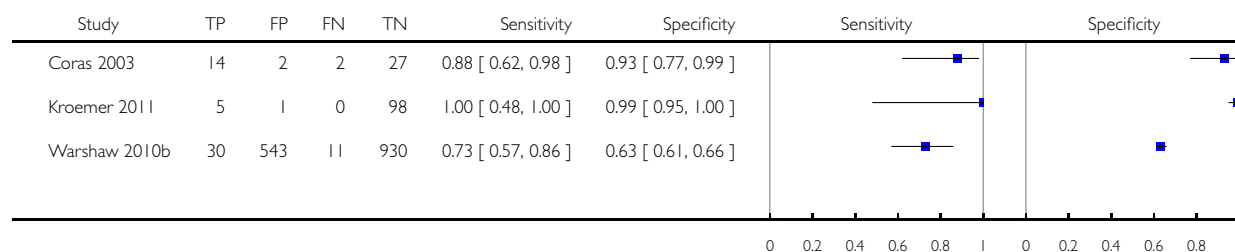

Test: 7 Teledermatology photographic + dermoscopic image vs histology (invasive melanoma or atypical intraepidermal melanocytic variants)

Test 8. Expert face-to-face (VI + dermoscopy) (invasive melanoma or atypical intraepidermal melanocytic variants).

Review: Teledermatology for diagnosing skin cancer in adults

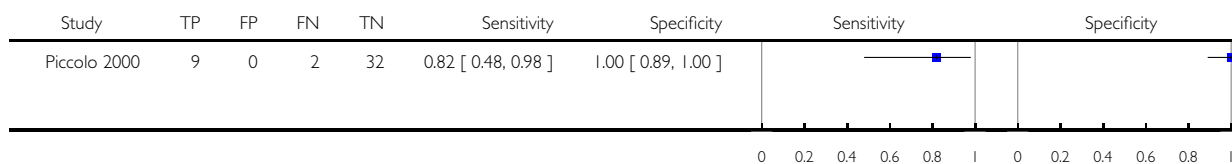

Test: 8 Expert face-to-face (VI + dermoscopy) (invasive melanoma or atypical intraepidermal melanocytic variants)

Test 9. Teledermatology - photographic + dermoscopic image vs histology (invasive melanoma).

Review: Teledermatology for diagnosing skin cancer in adults

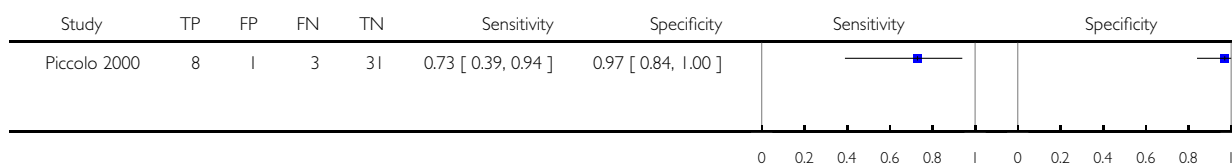

Test: 9 Teledermatology – photographic + dermoscopic image vs histology (invasive melanoma)

Test 10. Expert face-to-face (VI + dermoscopy) vs histology (invasive melanoma).

Review: Teledermatology for diagnosing skin cancer in adults

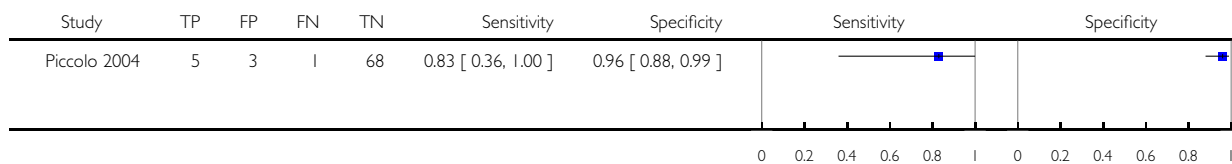

Test: 10 Expert face-to-face (VI + dermoscopy) vs histology (invasive melanoma)

Test 11. Teledermatology - dermoscopic image vs histology (acral melanoma).

Review: Teledermatology for diagnosing skin cancer in adults

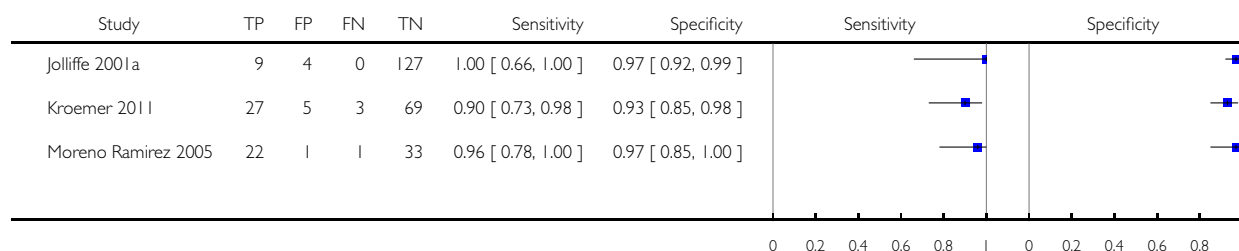

Test: 11 Teledermatology – dermoscopic image vs histology (acral melanoma)

Test 12. Teledermatology - photographic image vs histology (basal cell carcinoma (BCC)).

Review: Teledermatology for diagnosing skin cancer in adults

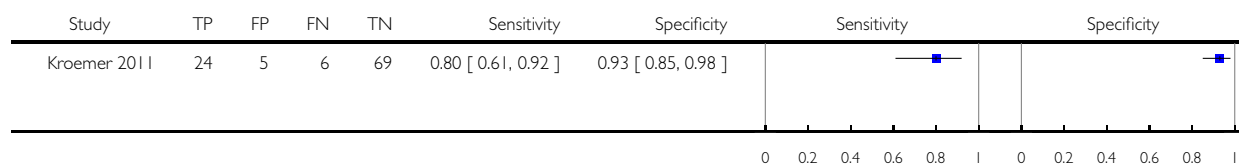

Test: 12 Teledermatology – photographic image vs histology (basal cell carcinoma (BCC))

Test 13. Teledermatology - dermoscopic image vs histology (BCC).

Review: Teledermatology for diagnosing skin cancer in adults

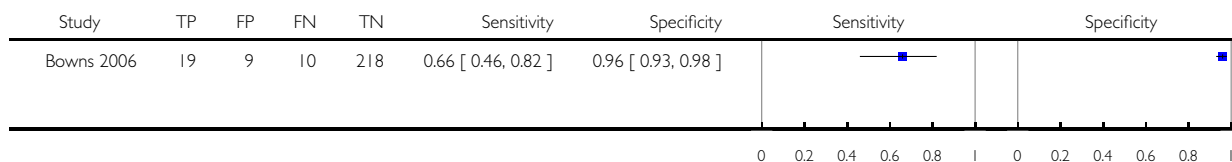

Test: 13 Teledermatology – dermoscopic image vs histology (BCC)

Test 14. Teledermatology - photographic + dermoscopic image vs histology (BCC).

Review: Teledermatology for diagnosing skin cancer in adults

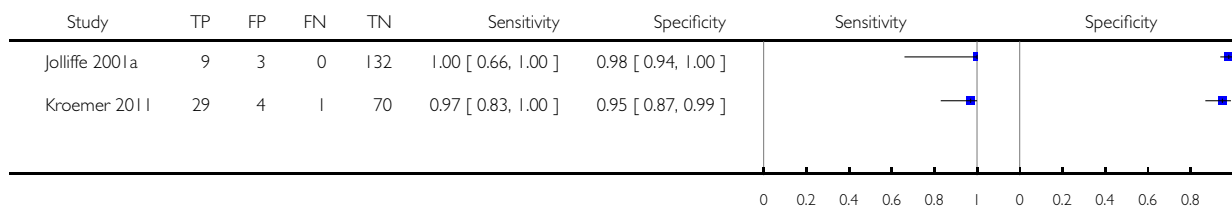

Test: 14 Teledermatology – photographic + dermoscopic image vs histology (BCC)

Test 15. Expert face-to-face (VI + dermoscopy) vs histology (BCC).

Review: Teledermatology for diagnosing skin cancer in adults

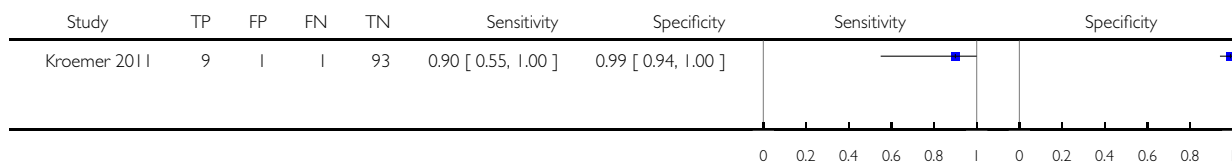

Test: 15 Expert face-to-face (VI + dermoscopy) vs histology (BCC)

Test 16. Teledermatology - photographic image vs histology (cutaneous squamous cell carcinoma (cSCC)).

Review: Teledermatology for diagnosing skin cancer in adults

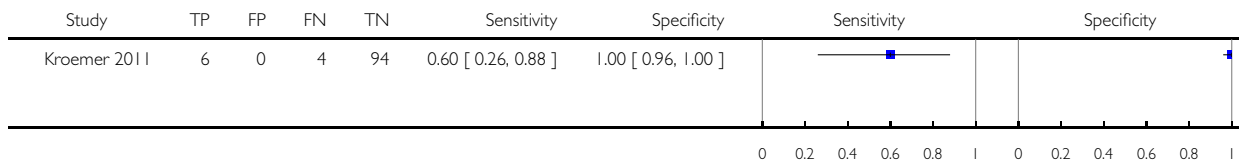

Test: 16 Teledermatology – photographic image vs histology (cutaneous squamous cell carcinoma (cSCC))

Test 17. Teledermatology - dermoscopic image vs histology (cSCC).

Review: Teledermatology for diagnosing skin cancer in adults

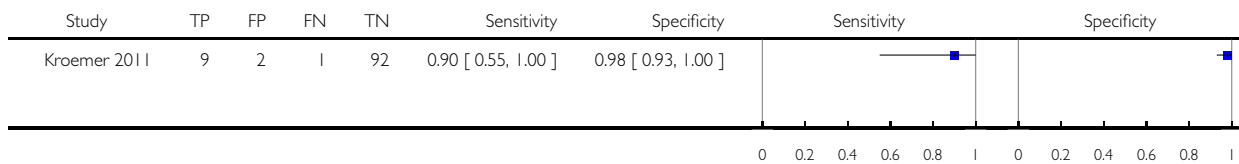

Test: 17 Teledermatology - dermoscopic image vs histology (cSCC)

Test 18. Expert face-to-face (VI + dermoscopy) vs histology (cSCC).

Review: Teledermatology for diagnosing skin cancer in adults

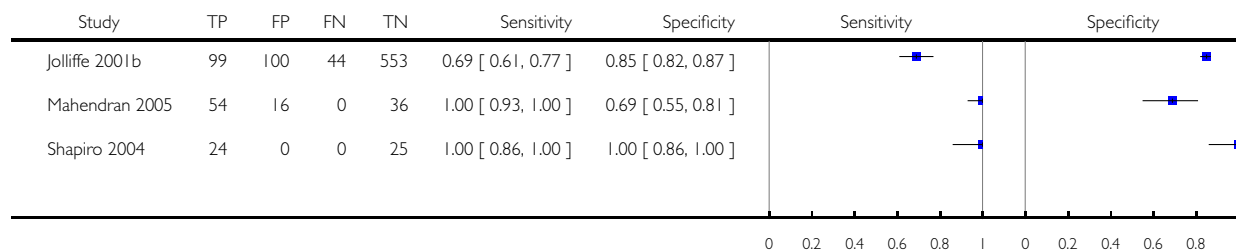

Test: 18 Expert face-to-face (VI + dermoscopy) vs histology (cSCC)

Test 19. Teledermatology - photographic image vs face-to-face clinical diagnosis (immediate action).

Review: Teledermatology for diagnosing skin cancer in adults

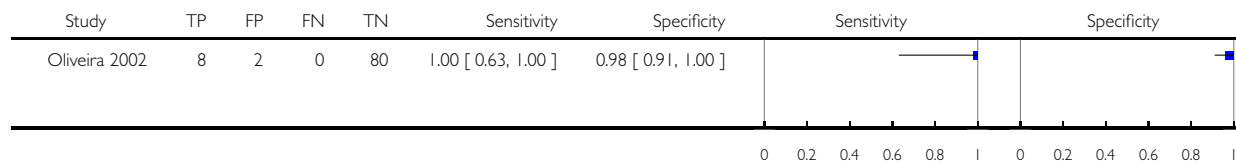

Test: 19 Teledermatology – photographic image vs face-to-face clinical diagnosis (immediate action)

Test 20. Teledermatology - photographic image vs face-to-face clinical diagnosis (of malignancy).

Review: Teledermatology for diagnosing skin cancer in adults

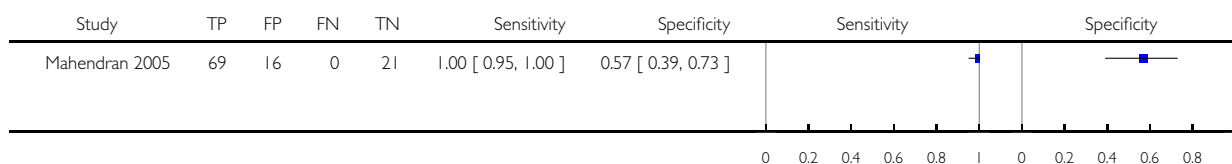

Test: 20 Teledermatology – photographic image vs face-to-face clinical diagnosis (of malignancy)

Test 21. Teledermatology - photographic image vs face-to-face clinical diagnosis (immediate action or follow-up).

Review: Teledermatology for diagnosing skin cancer in adults

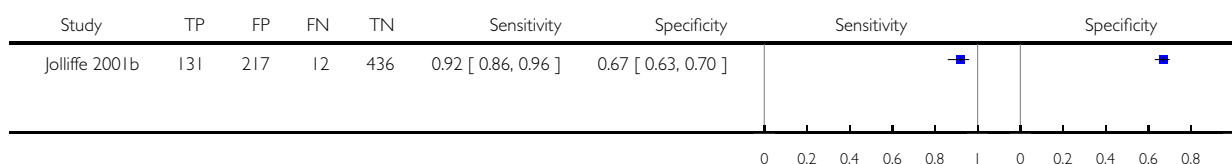

Test: 21 Teledermatology – photographic image vs face-to-face clinical diagnosis (immediate action or follow-up)

Test 22. Teledermatology - photographic image vs face-to-face clinical diagnosis (immediate action; registrar data).

Review: Teledermatology for diagnosing skin cancer in adults

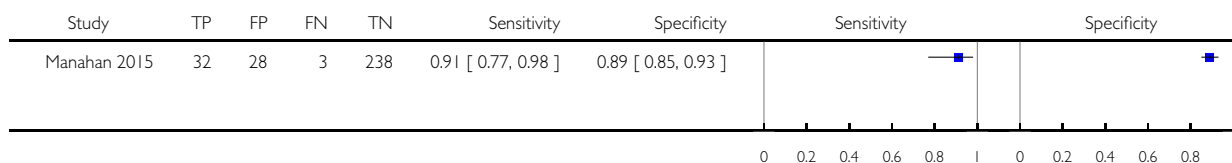

Test: 22 Teledermatology – photographic image vs face-to-face clinical diagnosis (immediate action; registrar data)

Studies of referral accuracy - TD vs expert FTF decision						
Jolliffe 2001b	-	-	-	-	-	Clin only (refer or not)
Mahendran 2005	-	-	-	-	-	Clin only (excise or not)
Manahan 2015	-	-	-	-	-	Clin/Derm (see FTF)

Table 1. Cross-tabulation of included studies against target condition assessed, by type of images used for teledermatology
(Continued)

Oliveira 2002	-	-	-	-	-	Clin only (dx as malignant)
Phillips 1998	-	-	-	-	-	Live link (dx as any SC; definitely/probably malignant/excise or not)
Shapiro 2004	-	-	-	-	-	Clin only (excise or not)

BCC: basal cell carcinoma; clin: clinical; cSCC: cutaneous squamous cell carcinoma; Derm: dermoscopic images; dx: diagnosis; FTF: face-to-face; GP: general practitioner; MiS: melanoma in situ (atypical intraepidermal melanocytic variants); MM: invasive melanoma; Photo: photographic images; SC: skin cancer; TD: teledermatology.

^aFace-to-face diagnosis by an expert/dermatologist unless otherwise stated.

^bAll include melanoma in situ as disease positive apart from [Piccolo 2000](#) and [Piccolo 2004](#), which reported detection of invasive melanoma only.

^cIncluded a direct comparison with expert face-to-face diagnosis versus histology.

Table 2. Summary estimates of sensitivity and specificity for teledermatology

Index test, ^a target condition	Studies	Cases/number of participants	Summary sensitivity (95% CI) %	Summary specificity (95% CI) %
Teledermatology photographic image, any	4	452/717	94.9 (90.1 to 97.4)	84.3 (48.5 to 96.8)
Teledermatology photographic/dermoscopic image, MM + MiS	4	93/664	85.4 (68.3 to 94.1)	91.6 (81.1 to 96.5)
Teledermatology photographic image vs histology, BCC	3	62/301	93.5 (84.0 to 97.6)	95.8 (92.4 to 97.7)

BCC: basal cell carcinoma; CI: confidence interval; MM + MiS: invasive melanoma and atypical intraepidermal melanocytic variants.

^aReference standard was histology for all comparisons.

Table 3. Direct comparisons of teledermatology with face-to-face diagnosis of melanoma and other types of skin cancer

Study	Sensitivity (true positives/cases) %		Difference (95% CI)	Specificity (true negatives/non cases) %		Difference (95% CI)

CI: confidence interval.

^adenotes statistically significant difference.

APPENDICES

Appendix I. Current content and structure of the Programme Grant

	LIST OF REVIEWS	Number of studies
	Diagnosis of melanoma	
1	Visual inspection	49
2	Dermoscopy +/- visual inspection	104
3	Teledermatology	22
4	Smartphone applications	2
5a	Computer-assisted diagnosis - dermoscopy-based techniques	42
5b	Computer-assisted diagnosis - spectroscopy-based techniques	Review amalgamated into 5a
6	Reflectance confocal microscopy	18
7	High-frequency ultrasound	5

(Continued)

Diagnosis of keratinocyte skin cancer (BCC and cSCC)		
8	Visual inspection +/- Dermoscopy	24
5c	Computer-assisted diagnosis - dermoscopy-based techniques	Review amalgamated into 5a
5d	Computer-assisted diagnosis - spectroscopy-based techniques	Review amalgamated into 5a
9	Optical coherence tomography	5
10	Reflectance confocal microscopy	10
11	Exfoliative cytology	9
Staging of melanoma		
12	Imaging tests (ultrasound, CT, MRI, PET-CT)	38
13	Sentinel lymph node biopsy	160
Staging of cSCC		
	Imaging tests review	Review dropped; only one study identified
13	Sentinel lymph node biopsy	Review amalgamated into 13 above (n = 15 studies)

Appendix 2. Glossary of terms

Term	Definition
Atypical intraepidermal melanocytic variant	Unusual area of darker pigmentation contained within the epidermis that may progress to an invasive melanoma; includes melanoma <i>in situ</i> and lentigo maligna
Atypical naevi	Unusual looking but non-cancerous mole or area of darker pigmentation of the skin
BRAF V600 mutation	BRAF is a human gene that makes a protein called B-Raf which is involved in the control of cell growth. BRAF mutations (damaged DNA) occur in around 40% of melanomas, which can then be treated with particular drugs
BRAF inhibitors	Therapeutic agents which inhibit the serine-threonine protein kinase BRAF-mutated metastatic melanoma

(Continued)

Breslow thickness	A scale for measuring the thickness of melanomas by the pathologist using a microscope, measured in millimetres from the top layer of skin to the bottom of the tumour
Congenital naevi	A type of mole found on infants at birth
Dermoscopy	Whereby a handheld microscope is used to allow more detailed, magnified, examination of the skin compared to examination by the naked eye alone
False negative	A person who is truly positive for a disease, but whom a diagnostic test classifies them as disease-free
False positive	A person who is truly disease-free, but whom a diagnostic test classifies them as having the disease
Histopathology/histology	The study of tissue, usually obtained by biopsy or excision, e.g. under a microscope
Incidence	The number of new cases of a disease in a given time period.
Index test	A diagnostic test under evaluation in a primary study.
Lentigo maligna	Unusual area of darker pigmentation contained within the epidermis which includes malignant cells but with no invasive growth. May progress to an invasive melanoma
Lymph node	Lymph nodes filter the lymphatic fluid (clear fluid containing white blood cells) that travels around the body to help fight disease; they are located throughout the body often in clusters (nodal basins)
Melanocytic naevus	An area of skin with darker pigmentation (or melanocytes) also referred to as 'moles.'
Meta-analysis	A form of statistical analysis used to synthesise results from a collection of individual studies
Metastases/metastatic disease	Spread of cancer away from the primary site to somewhere else through the bloodstream or the lymphatic system
Micrometastases	Micrometastases are metastases so small that they can only be seen under a microscope
Mitotic rate	Microscopic evaluation of number of cells actively dividing in a tumour
Morbidity	Detrimental effects on health
Mortality	Either the condition of being subject to death; or the death rate, which reflects the number of deaths per unit of population in relation to any specific region, age group, disease, treatment or other classification, usually expressed as deaths per

(Continued)

	100, 1000, 10,000 or 100,000 people
Multidisciplinary team	A team with members from different healthcare professions and specialties (e.g. urology, oncology, pathology, radiology and nursing). Cancer care in the National Health Service (NHS) uses this system to ensure that all relevant health professionals are engaged to discuss the best possible care for that patient
Prevalence	The proportion of a population found to have a condition.
Prognostic factors/indicators	Specific characteristics of a cancer or the person who has it which might affect the patient's prognosis
Receiver operating characteristic (ROC) analysis	The analysis of an ROC plot of a test to select an optimal threshold for test positivity
Receiver operating characteristic (ROC) plot	A plot of the sensitivity and 1 minus the specificity of a test at the different possible thresholds for test positivity; represents the diagnostic capability of a test with a range of binary test results
Recurrence	When new cancer cells are detected following treatment. This can occur either at the site of the original tumour or at other sites in the body
Reference standard	A test or combination of tests used to establish the final or 'true' diagnosis of a patient in an evaluation of a diagnostic test
Reflectance confocal microscopy (RCM)	A microscopic technique using infrared light (either in a handheld device or a static unit) that can create images of the deeper layers of the skin
Sensitivity	In this context the term is used to mean the proportion of people with a disease who have that disease correctly identified by the study test
Specificity	The proportion of people without the disease of interest (in this case with benign skin lesions) who have that absence of disease correctly identified by the study test
Staging	Clinical description of the size and spread of a patient's tumour, fitting into internationally agreed categories
Subclinical (disease)	Disease that is usually asymptomatic and not easily observable, e.g. by clinical or physical examination
Systemic treatment	Treatment, usually given by mouth or by injection, that reaches and affects cancer cells throughout the body rather than targeting 1 specific area

Appendix 3. Content of algorithms used to assist melanoma diagnosis by visual inspection alone

<p>ABCD (Friedman 1985; Rigel 1993; Pehamberger 1993)</p> <p>ABCDE (Carli 1994; Cristofolini 1994; Thomas 1998; Benelli 1999; Benelli 2001; Abbasi 2004)</p> <p>BCD (McGovern 1992)</p>	<p>Seven-point checklist (MacKie 1985; MacKie 1990; Keefe 1990)</p>	<p>Seven-point checklist (revised) (MacKie 1990; Healsmith 1994)</p>
<p>A - asymmetry</p> <ul style="list-style-type: none"> • variable centripetal growth of melanocytes (Friedman 1985) • “geometrical asymmetry in two axes of the tumour” (Benelli 1999; Benelli 2001; Thomas 1998) • “one half does not match the other half” (McGovern 1992); not separately scored in study “because we believed that asymmetry and border irregularity were linked” <p>B - irregular borders</p> <ul style="list-style-type: none"> • irregular shape with notching or scalloping of border (Friedman 1985) • “edges are ragged, notched, or blurred” (McGovern 1992) • “irregular and notched” (Cristofolini 1994) • “unsharp or ill-defined or angular” (Thomas 1998) • “ragged or indented” (Benelli 1999; Benelli 2001) <p>C - colour</p> <ul style="list-style-type: none"> • variable pigmentation, multiple colours; various of hues of brown, also black, blue, red and white (Friedman 1985) • “pigmentation is not uniform; shades of tan, brown and black are present with dashes of red, white, or blue” (McGovern 1992) • “mottled-haphazard display” (Cristofolini 1994) • “presence of at least two different colours within the lesion (with the exception of the usual symmetrical darkening of the lesion in its centre)” (Benelli 2001; Thomas 1998) • “multiple colours” (Abbasi 2004) <p>D - diameter ≥ 6 mm</p> <ul style="list-style-type: none"> • all studies agree 	<ul style="list-style-type: none"> • sensory change, (greater awareness of the lesion or mild itch); • diameter of ≥ 1 cm; • growth of the lesion; • an irregular edge; • irregular pigment with different shades of brown and black in the lesion; • inflammation • crusting, oozing or bleeding. <p>Presence of ≥ 3 suggestive of melanoma</p>	<p>MacKie 1990, Mackie 1991, and Healsmith 1994 describe the revised criteria as:</p> <p>Major signs</p> <ul style="list-style-type: none"> • Change in size • Change in shape • Change in colour <p>Minor signs</p> <ul style="list-style-type: none"> • Inflammation • Crusting or bleeding • Sensory change • Diameter ≥ 7 mm <p>“a patient with a pigmented lesion with any one of the major signs should be considered for referral and that the presence of any of the minor signs should be a further stimulus to referral.” (MacKie 1990)</p>

(Continued)

<p>E - evolution</p> <ul style="list-style-type: none">• “changes in pigmentation” (Cristofolini 1994)• “enlargement of the surface (and not in height) of the lesion; anamnestic criterion based on the patient’s description of the natural history of the lesion” (Thomas 1998)• “elevation, enlargement or change in the colour of the lesion” (Benelli 1999; Benelli 2001)• “evolving (with respect to size, shape, shades of colour, surface features, or symptoms)” (Abbasi 2004) <p>McGovern 1992 described 7 characteristics as: “increasing size, variegation, inflammation, irregular outline, greater than 1cm diameter, itch, bleeding.”</p> <p>These are expanded on in MacKie 1990, who described the original (MacKie 1985) criteria as:</p> <ul style="list-style-type: none">• sensory change, often described as a greater awareness of the lesion but also as a mild itch;• diameter of ≥ 1 cm;• growth of the lesion;• an irregular edge;• irregular pigment with different shades of brown and black in the lesion;• inflammation (a reddish tinge within the lesion);• crusting, oozing or bleeding.• ≥ 3 criteria should prompt referral (MacKie 1990)		
--	--	--

Appendix 4. Proposed sources of heterogeneity

1. Population characteristics

- General versus higher risk populations
- Participant population: primary/secondary/specialist unit
- Lesion suspicion: general suspicion/atypical/equivocal/NR
- Lesion type: any pigmented; melanocytic
- Inclusion of multiple lesions per participant
- Ethnicity

2. Index test characteristics

- Nature of, and definition of, criteria for test positivity
- Observer experience with the index test
- Approaches to lesion preparation (e.g. the use of oil or antiseptic gel for dermoscopy)

3. Reference standard characteristics

- Reference standard used
- Whether histology-reporting meets pathology-reporting guidelines
- Use of excisional versus diagnostic biopsy
- Whether two independent dermatopathologists reviewed histological diagnosis

4. Study quality

- Consecutive or random sample of participants recruited
- Index test interpreted blinded to the reference standard result
- Index test interpreted blinded to the result of any other index test
- Presence of partial or differential verification bias (whereby only a sample of those subject to the index test are verified by the reference test or by the same reference test with selection dependent on the index test result)
 - Use of an adequate reference standard
 - Overall risk of bias

Appendix 6. Full-text inclusion criteria

Criterion	Inclusion	Exclusion
Study design	For diagnostic and staging reviews <ul style="list-style-type: none"> Any study for which a 2x2 contingency table can be extracted, e.g. <ul style="list-style-type: none"> diagnostic case control studies 'cross-sectional' test accuracy study with retrospective or prospective data collection studies where estimation of test accuracy was not the primary objective but test results for both index and reference standard were available RCTs of tests or testing strategies where participants were randomised between index tests and all undergo a reference standard (i.e. accuracy RCTs) 	<ul style="list-style-type: none"> < 5 melanoma cases (diagnosis reviews) < 10 participants (staging reviews) Studies developing new criteria for diagnosis unless a separate 'test set' of images were used to evaluate the criteria (mainly digital dermoscopy) Studies using 'normal' skin as controls Letters, editorials, comment papers, narrative reviews Insufficient data to construct a 2x2 table
Target condition	<ul style="list-style-type: none"> Melanoma Keratinocyte skin cancer (or non-melanoma skin cancer) BCC or epithelioma cSCC 	<ul style="list-style-type: none"> Studies exclusively conducted in children Studies of non-cutaneous melanoma or SCC
Population	For diagnostic reviews <ul style="list-style-type: none"> Adults with a skin lesion suspicious for melanoma, BCC or cSCC (other terms include pigmented skin lesion/nevi, melanocytic, keratinocyte, etc.) Adults at high risk of developing melanoma skin cancer, BCC or cSCC 	<ul style="list-style-type: none"> People suspected of other forms of skin cancer Studies conducted exclusively in children

(Continued)

	<p>For staging reviews</p> <ul style="list-style-type: none"> Adults with a diagnosis of melanoma or cSCC undergoing tests for staging of lymph nodes or distant metastases or both 	
Index tests	<p>For diagnosis</p> <ul style="list-style-type: none"> Visual inspection/clinical examination Dermoscopy/dermatoscopy Teledermoscopy Smartphone/mobile phone applications Digital dermoscopy/artificial intelligence Confocal microscopy Ocular coherence tomography Exfoliative cytology High-frequency ultrasound Canine odour detection DNA expression analysis/gene chip analysis Other <p>For staging</p> <ul style="list-style-type: none"> CT PET PET-CT MRI Ultrasound +/-FNAC SLNB +/-high-frequency ultrasound Other <p>Any test combination and in any order Any test positivity threshold Any variation in testing procedure (e.g. radioisotope used)</p>	<ul style="list-style-type: none"> Sentinel lymph biopsy for therapeutic rather than staging purposes Tests to determine melanoma thickness Tests to determine surgical margins/lesion borders Tests to improve histopathology diagnose LND
Reference standard	<p>For diagnostic studies</p> <ul style="list-style-type: none"> Histopathology of the excised lesion Clinical follow-up of non-excised/benign appearing lesions with later histopathology if suspicious Expert diagnosis (studies should not be included if expert diagnosis is the sole reference standard) <p>For studies of imaging tests for staging</p> <ul style="list-style-type: none"> Histopathology (via LND or SLMB) Clinical/radiological follow-up A combination of the above <p>For studies of SLNB accuracy for staging</p> <ul style="list-style-type: none"> LND of both SLN+ and SLn participants to identify all diseased nodes LND of SLN+ participants and follow-up of SLN participants to identify a subsequent nodal recurrence in a <i>previously investigated</i> nodal basin 	<p>For diagnostic studies</p> <ul style="list-style-type: none"> Exclude if any disease-positive participants have diagnosis unconfirmed by histology Exclude if > 50% of disease-negative participants have diagnosis confirmed by expert opinion with no histology or follow-up Exclude studies of referral accuracy, i.e. comparing referral decision with expert diagnosis, unless evaluations of teledermatology or mobile phone applications

(Continued)

BCC: basal cell carcinoma; cSCC: cutaneous squamous cell carcinoma; CT: computed tomography; FNAC: fine needle aspiration cytology; LND: lymph node dissection; MRI: magnetic resonance imaging; PET: positron emission tomography; PET-CT: positron emission tomography computed tomography; RCT: randomised controlled trial; SCC: squamous cell carcinoma; SLN+: positive sentinel lymph node; SLn: negative sentinel lymph node; SLNB: sentinel lymph node biopsy

Appendix 7. Quality assessment (based on QUADAS-2)

The QUADAS-2 checklist was tailored to the review topic as follows below (Whiting 2011).

Participant selection domain (1)

Selective recruitment of study participants can be a key influence on test accuracy. In general terms, all participants eligible to undergo a test should be included in a study, allowing for the intended use of that test within the context of the study. We considered studies that separately sampled malignant and benign lesions to have used a case-control design; and those that supplemented a series of suspicious lesions with additional malignant or benign lesions to be at unclear risk of bias.

In terms of exclusions, we considered studies that excluded particular lesion types (e.g. lentigo maligna), particular lesion sites, or that excluded lesions on the basis of image quality or lack of observer agreement (e.g. on histopathology) to be at high risk of bias.

In judging the applicability of patient populations to the review question, we considered restriction to particular lesion populations, such as melanocytic, nodular, high risk or restrictions by size or to lesions that had been excised to be of high concern for applicability. For teledermatology, lesions selected from referred populations rather than selected by general practitioners (GPs) in a primary care setting were also judged to be high concern for applicability.

Given that diagnosis of skin cancer is primarily lesion-based, there is the potential for study participants with multiple lesions to contribute disproportionately to estimates of test accuracy, especially if they are at particular risk of having skin cancer. We considered studies that include a high number of lesions in relation to the number of participants in the study to be less representative than studies conducted in a more general population of participants (i.e. if the difference between the number of included lesions and number of included participants is greater than 5%).

Index test domain (2)

Given the potential for subjective differences in test interpretation for melanoma, the interpretation of the index test blinded to the result of the reference standard is a key means of reducing bias. For prospective studies and retrospective studies that used the original index test interpretation, the diagnosis will by nature be interpreted and recorded before the result of the reference standard is known; however, studies using previously acquired images could be particularly susceptible to information bias. For these studies to be at low risk of bias, we required a clear indication that observers were unaware of the reference standard diagnosis at time of test interpretation. An item was also added to assess the presence of blinding between interpretations of different algorithms; however this item was not included in the overall assessment of risk of bias.

Prespecification of the index test threshold was considered present if the study clearly reported that the threshold used was not data driven, i.e. was not based on study results. Studies that did not clearly describe the threshold used but that required clinicians to record a diagnosis or management decision for a lesion were considered to be unclear on this criterion. Studies reporting accuracy for multiple numeric thresholds, where receiver operating characteristic (ROC) analysis was used to select the threshold, or that reported accuracy for the presence of independently significant lesion characteristics with no separate test set of lesions were considered at high risk of bias.

In terms of applicability of the index test to the review question, we required images for teledermatology assessment to be acquired in primary settings by GPs or other primary care staff rather than by expert dermatologists or medical photographers in a specialist setting. We also required diagnosis to be made by a single observer as opposed to a consensus decision or mean across multiple observers.

Despite the often subjective nature of test interpretation, it is also important for study authors to outline the particular lesion characteristics that were considered to be indicative for melanoma, for basal cell carcinoma (BCC) or for cutaneous squamous cell carcinoma (cSCC), particularly where established algorithms or checklists were not used. Studies were considered of low concern if the threshold used was established in a prior study or sufficient threshold details were presented to allow replication.

Reference standard domain (3)

In an ideal study, consecutively recruited participants should all undergo incisional or excisional biopsy of the skin lesion regardless of level of clinical suspicion of melanoma. In reality, both partial and differential verification bias are likely. Partial verification bias may occur where histology is the only reference standard used, and only those participants with a certain degree of suspicion of malignancy

based on the result of the index test undergo verification, the others either being excluded from the study or defined as being disease-negative without further assessment or follow-up, as discussed above.

Differential verification bias will be present where other reference standards are used in addition to histological verification of suspicious lesions. A typical example of verification bias in skin cancer occurs when investigators do not biopsy people with benign-appearing lesions but instead follow them up for a period of time to determine whether any malignancy subsequently develops (these would be false-negatives on the index test). We defined an 'adequate' reference standard as: all disease-positive people having a histological reference standard either at the time of application of the index test or after a period of clinical follow-up; and at least 80% of disease-negative participants have received a histological diagnosis, with up to 20% undergoing at least three months' follow-up of benign-appearing lesions.

A further challenge is the potential for incorporation bias, i.e. where the result of the index test is used to help determine the reference standard diagnosis. It is normal practice for the clinical diagnosis (usually by visual inspection or dermoscopy) to be included on pathology request forms and for the histopathologist to use this diagnosis to help with the pathology interpretation. Although inclusion of such clinical information on the histopathology request form is theoretically a form of incorporation bias, blinded interpretation of the histopathology reference standard is not normal practice, and enforcement of such conditions would significantly limit the generalisability of the study results. For studies comparing teledermatology against a histological reference standard, this item was therefore scored but did not contribute to the overall risk of bias. For studies comparing teledermatology against a face-to-face expert diagnosis, however, this item was scored and did contribute to overall risk of bias.

In judging the applicability of the reference standard to our review question, scored studies as high concern around applicability if they used expert diagnosis (with no follow-up) as a reference standard in any patient, or did not report histology interpretation by a dermatopathologist.

Flow and timing domain (4)

In the ideal study, the acquisition of images for the teledermatology diagnosis and the reference standard diagnosis should be made consecutively or as near to each other in time as possible to avoid changes in lesion over time. We have defined a one-month period as an appropriate interval between application of the index test and the reference standard (either histological or face-to-face). For studies using clinical follow-up, a minimum three-month follow-up period has been defined as at low risk of bias for detecting false-negatives. This interval was chosen based on a study showing that most false-negative melanomas will be diagnosed within three months of the initial negative index test although a small number will be diagnosed up to 12 months subsequently ([Altamura 2008](#)).

In assessing whether all patients were included in the analysis, we considered studies at high risk of bias if participants were excluded following recruitment.

Item	Response (delete as required)
Participant selection (1) -risk of bias	
1. Was a consecutive or random sample of participants or images enrolled?	Yes - if paper states consecutive or random No - if paper describes other method of sampling Unclear - if participant sampling not described
2. Was a case-control design avoided? (note: a diagnostic case-control study separately recruits participants according to selected final diagnoses, e.g. those with melanoma, with BCC, with severe dysplasia and with mild dysplasia AND will usually deliberately sample certain numbers from each group such that the overall case mix of included participants and disease prevalence is not reflective of usual care.)	Yes - if case-control design clearly not used No - if study described as case-control or describes sampling specific numbers of participants with particular diagnoses Unclear - if not clearly described or you have any concerns that the authors have not selected a series of participants
3. Did the study avoid inappropriate exclusions, e.g. <ul style="list-style-type: none"> • 'difficult to diagnose' lesions not excluded • lesions not excluded on basis of disagreement between evaluators or histopathologists 	Yes - if inappropriate exclusions were avoided No - if lesions were excluded that might affect test accuracy, e.g. 'difficult to diagnose' lesions, OR where disagreement between evaluators was observed

(Continued)

	Unclear - if not clearly reported but there is suspicion that difficult to diagnose lesions may have been excluded
<p>Could the selection of participants have introduced bias? <i>If answers to all of questions 1. AND 2. AND 3. 'Yes'</i> <i>If answers to any 1 of questions 1. OR 2. OR 3. 'No'</i> <i>If answers to any 1 of questions 1. OR 2. OR 3. 'Unclear'</i></p>	<p>Risk is low Risk is high Risk is unclear</p>
Participant selection (1) -concerns regarding applicability	
<p>1. Are the included participants and chosen study setting appropriate to answer the review question, i.e. are the study results generalisable? This item is not asking whether exclusion of certain participant groups might bias the study's results (as in 'Risk of bias' above), but is asking whether the chosen study participants and setting are appropriate to answer our review question. Because we are looking to establish test accuracy in both primary presentation and referred participants, a study could be appropriate for 1 setting and not for the other, or it could be unclear as to whether the study can appropriately answer either question</p>	<p>Yes - if participants included in the study appear to be generally representative of those who might present in a usual practice setting No - if study participants were restricted to those in lesion sub-groups, e.g. melanocytic only, or small lesions only, if only excised lesions were included, or lesions were selected from referred populations rather than selected by general practitioners in a primary care setting Unclear - if insufficient details are provided to determine the generalisability of study participants</p>
<p>2. Did the study avoid including participants with multiple lesions?</p>	<p>Yes - if the difference between the number of included lesions and number of included participants is less than 5% No - if the difference between the number of included lesions and number of included participants is greater than 5% Unclear - if it is not possible to assess</p>
<p>Is there concern that the included participants do not match the review question? <i>If the answer to question 1. and 2. 'Yes'</i> <i>If the answer to question 1. or 2. 'No'</i> <i>If the answer to question 1. or 2. 'Unclear'</i></p>	<p>Concern is low Concern is high Concern is unclear</p>
Index test (2) -risk of bias (to be completed per test evaluated)	
<p>1. Was the index test or testing strategy result interpreted without knowledge of the results of the reference standard?</p>	<p>Yes - if index test described as interpreted without knowledge of the reference standard result or, for prospective studies, if index test is always conducted and interpreted prior to the reference standard No - if index test described as interpreted in knowledge of reference standard result Unclear - if index test blinding is not described</p>
<p>2. Was the diagnostic threshold at which the test was considered positive (i.e. melanoma, BCC or cSCC present) prespecified?</p>	<p>Yes - if threshold was prespecified (i.e. prior to analysing study results), i.e. results were not data driven No - if threshold was not prespecified but was selected after analysis of results usually to maximise sensitivity or specificity (or both), or multiple thresholds were tested</p>

(Continued)

	Unclear - if not possible to tell whether or not diagnostic threshold was prespecified
<p>Could the conduct or interpretation of the index test have introduced bias?</p> <p>For NC and BPC studies</p> <p><i>If answers to questions 1. and 2. 'Yes'</i></p> <p><i>If answers to either questions 1. or 2. 'No'</i></p> <p><i>If answers to either questions 1). or 2. 'Unclear'</i></p> <p>For WPC studies</p> <p><i>If answers to all questions 'Yes'</i></p> <p><i>If answers to any 1 question 'No'</i></p> <p><i>If answers to any 1 of questions is 'Unclear'</i></p>	<p>For NC and BPC studies</p> <p>Risk is low</p> <p>Risk is high</p> <p>Risk is unclear</p> <p>For WPC studies</p> <p>Risk is low</p> <p>Risk is high</p> <p>Risk is unclear</p>
Index test (2) -concern about applicability	
1. Was the test applied and interpreted in a clinically applicable manner?	<p>Yes - in-person evaluation and single observer result present</p> <p>No - image based, or mean or consensus result presented, or both</p> <p>Unclear - if cannot tell</p>
<p>2. Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?</p> <p>Study results can only be reproduced if the diagnostic threshold is described in sufficient detail. This item applies equally to studies using pattern recognition and those using checklists or algorithms to aid test interpretation</p>	<p>Yes - if the criteria for diagnosis of the target disorder were reported in sufficient detail to allow replication. If the study does not describe the threshold in detail BUT evaluates an established test/algorithm AND provides a citation to a previous study of the test in the Methods or Results, then respond Yes</p> <p>No - if the criteria for diagnosis of the target disorder were not reported in sufficient detail to allow replication</p> <p>Unclear - if some but not sufficient information on criteria for diagnosis to allow replication were provided. If the study does not describe the threshold in detail BUT evaluates an established test/algorithm but with NO citation to a previous study of the test in the methods, then respond Unclear</p>
3) Was the test interpretation carried out by an experienced examiner?	<p>Yes - if the test was interpreted by ≥ 1 speciality accredited dermatologists, or by examiners of any clinical background with special interest in dermatology and with any formal training in the use of the test</p> <p>No - if the test was not interpreted by an experienced examiner (see above)</p> <p>Unclear - if the experience of the examiner(s) was not reported in sufficient detail to judge OR if examiners described as 'Expert' with no further detail given</p> <p>N/A - if system-based diagnosis, i.e. no observer interpretation</p>
<p>Is there concern that the index test, its conduct, or interpretation differ from the review question?</p> <p><i>If answers to questions 1., 2. AND 3. 'Yes'</i></p> <p><i>If answers to questions 1., 2. OR 3. 'No'</i></p> <p><i>If answers to questions 1., 2. OR 3. 'Unclear'</i></p>	<p>Concern is low</p> <p>Concern is high</p> <p>Concern is unclear</p>

(Continued)

Reference standard (3) -risk of bias	
<p>1). Is the reference standard likely to correctly classify the target condition?</p> <p>a) Disease positive - ≥ 1 of:</p> <ul style="list-style-type: none"> • Histological confirmation of the target disorder following biopsy or lesion excision • Clinical follow-up of benign appearing lesions following the application of the index test, leading to a histological diagnosis of the target disorder of interest: <ul style="list-style-type: none"> ◦ ≥ 3 months for melanoma or cSCC ◦ ≥ 6 months for BCC <p>b) Disease negative - ≥ 1 of:</p> <ul style="list-style-type: none"> • Histological confirmation of absence of the target disorder following biopsy or lesion excision in $\geq 80\%$ of disease-negative participants • Clinical follow up of benign appearing lesions following the index test in up to 20% of disease negative participants of: <ul style="list-style-type: none"> ◦ ≥ 3 months for melanoma or cSCC ◦ ≥ 6 months for BCC 	<p>a) Disease positive</p> <p>Yes - if all disease-positive participants underwent 1 of the listed reference standards</p> <p>No - if a final diagnosis for any disease-positive participant was reached without histopathology</p> <p>Unclear - if the method of final diagnosis was not reported for any disease-positive participant OR if the length of clinical follow-up used was not clear OR if a clinical follow-up reference standard was reported in combination with a participant-based analysis and it was not possible to determine whether the detection of a malignant lesion during follow-up is the same lesion that originally tested negative on the index test</p> <p>a) Disease negative</p> <p>Yes - if $\geq 80\%$ of benign diagnoses were reached by histology and up to 20% were reached by clinical follow-up of for a minimum of 3 (or 6) months following the index test</p> <p>No - if $> 20\%$ of benign diagnoses were reached by clinical follow-up of a minimum of 3 (or 6) months following the index test OR if clinical follow-up period was less than 3 (or 6) months</p> <p>Unclear - if the method of final diagnosis was not reported for any participant with benign or disease-negative diagnosis</p>
<p>2. Were the reference standard results interpreted without knowledge of the results of the index test?</p> <p><i>Please score this item for all studies. Response to the item will not be incorporated into the overall risk of bias assessment for comparisons against a histological reference standard as histopathology interpretation is usually conducted with knowledge of the clinical diagnosis (from visual inspection or dermoscopy (or both)). Response to the item will be incorporated into the overall risk of bias assessment for comparisons against a face-to-face reference standard</i></p>	<p>For studies comparing teledermatology against a histological reference standard</p> <p>Yes - if the histological reference standard diagnosis was reached blinded to the index test result</p> <p>No - if the histological reference standard diagnosis was reached with knowledge of the index test result</p> <p>Unclear - if blinded reference test interpretation was not clearly reported</p> <p>If the histopathologist is described as 'blinded' with no further detail as to whether the blinding applies to both index test or to clinical information (prior testing), we will assume that blinding is to the index test result only, unless further detail is provided</p> <p>For studies comparing teledermatology against a face-to-face expert diagnosis</p> <p>Yes - if the face-to-face reference standard diagnosis was described as interpreted without knowledge of the teledermatology diagnosis (e.g. the remote and face-to-face diagnosis was made by 2 different dermatologists)</p> <p>No - if the face-to-face reference standard diagnosis was made with knowledge of the teledermatology diagnosis or was made by the same dermatologist within a month of the remote image-based diagnosis</p> <p>Unclear - if it is not possible to tell whether knowledge of the teledermatology diagnosis could have influenced the reference standard diagnosis</p>

CONTRIBUTIONS OF AUTHORS

JD was the contact person with the editorial base.

JD and NC co-ordinated contributions from the coauthors and wrote the final draft of the review.

SB conducted the literature searches.

JD, NC, OB and JM screened papers against eligibility criteria.

JD and NC obtained data on ongoing and unpublished studies.

JD, NC, OB and JM appraised the quality of papers.

JD, NC, OB and JM extracted data for the review and sought additional information about papers.

JD and NC entered data into Review Manager 5.

JD, NC and YT analysed and interpreted data.

JD, JJD, NC, YT and CD worked on the methods sections.

JD, FW, RM, OB, JM, RNM and HCW drafted the clinical sections of the background and responded to the clinical comments of the referees.

JD, JJD, CD and YT responded to the methodology and statistics comments of the referees.

KG and CO'S were the consumer coauthors and checked the review for readability and clarity, as well as ensuring outcomes are relevant to consumers.

JD is the guarantor of the update.

Disclaimer

This project was supported by the National Institute for Health Research (NIHR), via Cochrane Infrastructure funding to the Cochrane Skin Group and Cochrane Programme Grant funding. DECLARATIONS OF INTEREST

NC: nothing to declare.

JD: nothing to declare.

YT: nothing to declare.

RNM: “my institution received a grant for a Barco NV commercially sponsored study to evaluate digital dermoscopy in the skin cancer clinic. My institution also received Oxfordshire Health Services Research Charitable Funds for carrying out a study of feasibility of using the Skin Cancer Quality of Life Impact Tool (SCQOLIT) in non melanoma skin cancer. I have received royalties for the Oxford Handbook of Medical Dermatology (Oxford University Press). I have received payment from Public Health England for the “Be Clear on Cancer” skin cancer report. I have no conflicts of interest to declare that directly relate to the publication of this work.”

SB: nothing to declare.

CD: nothing to declare.

JM: nothing to declare.

OB: nothing to declare.

KG: nothing to declare.

CO: nothing to declare.

FW: nothing to declare.

RM: nothing to declare.

JJD: nothing to declare.

HCW: I am director of the NIHR HTA Programme. HTA is part of the NIHR which also supports the NIHR systematic reviews programme from which this work is funded.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Due to the small number of studies available, a single review has been produced that evaluated the accuracy of teledermatology in all skin cancers; this replaces the two reviews intended in the protocols to separately address cutaneous melanoma and keratinocyte cancers.

Primary objectives and primary target condition have been changed from detection of cutaneous invasive melanoma alone and detection of BCC or cSCC as per the two protocols, to the detection of any skin cancer, as the appropriate triage of any malignant skin lesion to specialist care is the key issue for teledermatology. The detection of the target condition of invasive melanoma alone has instead been included as a secondary objective.

Heterogeneity investigations and sensitivity analyses were limited by the data available.

We amended the text to clarify that studies available only as conference abstracts would be excluded from the review unless full papers could be identified; studies available only as conference abstracts do not allow a comprehensive assessment of study methods or methodological quality.

We proposed to supplement the database searches by searching the annual meetings of appropriate organisations (e.g. British Association of Dermatologists Annual Meeting, American Academy of Dermatology Annual Meeting, European Academy of Dermatology and Venereology Meeting, Society for Melanoma Research Congress, World Congress of Dermatology, European Association of Dermato Oncology); however, due to volume of evidence retrieved from database searches and time restrictions we were unable to do this.

For quality assessment, the QUADAS-2 tool was further tailored according to the review topic. In terms of analysis, restriction to analysis of per participant data was not performed due to lack of data.
