#### ABSTRACT

#### Background

Adolescent overweight and obesity has increased globally, and can be associated with short- and long-term health consequences. Modifying known dietary and behavioural risk factors through behaviour changing interventions (BCI) may help to reduce childhood overweight and obesity. This is an update of a review published in 2009.

#### Objectives

To assess the effects of diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years.

#### Search methods

We performed a systematic literature search in: CENTRAL, MEDLINE, Embase, PsycINFO, CINAHL, LILACS, and the trial registers ClinicalTrials.gov and ICTRP Search Portal. We checked references of identified studies and systematic reviews. There were no language restrictions. The date of the last search was July 2016 for all databases.

#### Selection criteria

We selected randomised controlled trials (RCTs) of diet, physical activity and behavioural interventions for treating overweight or obesity in adolescents aged 12 to 17 years.

#### Data collection and analysis

Two review authors independently assessed risk of bias, evaluated the overall quality of the evidence using the GRADE instrument and extracted data following the guidelines of the *Cochrane Handbook for Systematic Reviews of Interventions*. We contacted trial authors for additional information.

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) I Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### Main results

We included 44 completed RCTs (4781 participants) and 50 ongoing studies. The number of participants in each trial varied (10 to 521) as did the length of follow-up (6 to 24 months). Participants ages ranged from 12 to 17.5 years in all trials that reported mean age at baseline. Most of the trials used a multidisciplinary intervention with a combination of diet, physical activity and behavioural components. The content and duration of the intervention, its delivery and the comparators varied across trials. The studies contributing most information to outcomes of weight and body mass index (BMI) were from studies at a low risk of bias, but studies with a high risk of bias provided data on adverse events and quality of life.

The mean difference (MD) of the change in BMI at the longest follow-up period in favour of BCI was -1.18 kg/m<sup>2</sup> (95% confidence interval (CI) -1.67 to -0.69); 2774 participants; 28 trials; low quality evidence. BCI lowered the change in BMI z score by -0.13 units (95% CI -0.21 to -0.05); 2399 participants; 20 trials; low quality evidence. BCI lowered body weight by -3.67 kg (95% CI -5.21 to - 2.13); 1993 participants; 20 trials; moderate quality evidence. The effect on weight measures persisted in trials with 18 to 24 months' follow-up for both BMI (MD -1.49 kg/m<sup>2</sup> (95% CI -2.56 to -0.41); 760 participants; 6 trials and BMI z score MD -0.34 (95% CI - 0.66 to -0.02); 602 participants; 5 trials).

There were subgroup differences showing larger effects for both BMI and BMI z score in studies comparing interventions with no intervention/wait list control or usual care, compared with those testing concomitant interventions delivered to both the intervention and control group. There were no subgroup differences between interventions with and without parental involvement or by intervention type or setting (health care, community, school) or mode of delivery (individual versus group).

The rate of adverse events in intervention and control groups was unclear with only five trials reporting harms, and of these, details were provided in only one (low quality evidence). None of the included studies reported on all-cause mortality, morbidity or socioeconomic effects.

BCIs at the longest follow-up moderately improved adolescent's health-related quality of life (standardised mean difference 0.44 ((95% CI 0.09 to 0.79); P = 0.01; 972 participants; 7 trials; 8 comparisons; low quality of evidence) but not self-esteem.

Trials were inconsistent in how they measured dietary intake, dietary behaviours, physical activity and behaviour.

#### Authors' conclusions

We found low quality evidence that multidisciplinary interventions involving a combination of diet, physical activity and behavioural components reduce measures of BMI and moderate quality evidence that they reduce weight in overweight or obese adolescents, mainly when compared with no treatment or waiting list controls. Inconsistent results, risk of bias or indirectness of outcome measures used mean that the evidence should be interpreted with caution. We have identified a large number of ongoing trials (50) which we will include in future updates of this review.

#### PLAIN LANGUAGE SUMMARY

#### Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years

#### **Review question**

How effective are diet, physical activity and behavioural interventions in reducing the weight of overweight or obese adolescents aged 12 to 17 years?

#### Background

Across the world, more adolescents are becoming overweight and obese. These adolescents are more likely to suffer from health problems in later life. More information is needed about what works best in treating this problem.

#### Study characteristics

We found 44 randomised controlled trials (clinical studies where people are randomly put into one of two or more treatment groups) comparing diet, physical activity and behavioural (where habits are changed or improved) treatments (interventions) to a variety of control groups delivered to 4781 overweight or obese adolescents aged 12 to 17 years. Our systematic review reports on the effects of multidisciplinary interventions, dietary interventions and physical activity interventions compared with a control group (no

intervention, 'usual care,' enhanced usual care or some other therapy if it was also delivered to the intervention group). The adolescents in the included studies were monitored (called follow-up) for between six months and two years.

#### Key results

The average age of adolescents ranged from 12 to 17.5 years. Most studies reported the body mass index (BMI). BMI is a measure of body fat and is calculated by dividing weight (in kilograms) by the square of the body height measured in metres (kg/m<sup>2</sup>). We summarised the results of 28 studies in 2774 adolescents reporting BMI, which on average was 1.18 kg/m<sup>2</sup> lower in the intervention groups compared with the control groups. We summarised the results of 20 studies in 1993 adolescents reporting weight, which on average was 3.67 kg lower in the intervention groups compared with the control groups. BMI reduction was maintained at 18 to 24 months of follow-up (monitoring participants until the end of the study), which on average was 1.49 kg/m<sup>2</sup> lower in the intervention groups compared with their life and health) but we did not find firm evidence of an advantage or disadvantage of these interventions for improving self-esteem, physical activity and food intake. No study reported on death from any cause, morbidity (illnesses) or socioeconomic effects (such as days away from school). Three studies reported no side effects, one reported no serious side effects, one did not provide details of side effects and the rest of the studies did not report whether side effects occurred or not.

We identified 50 ongoing studies which we will include in future updates of our review.

#### Currentness of evidence

This evidence is up to date as of July 2016.

#### Quality of the evidence

The overall quality of the evidence was rated as low for most of the outcomes (results) measured, mainly because of limited confidence in how studies were performed, inconsistent results between the studies and the way that some outcomes used do not capture obesity outcomes directly. Also, there were just a few studies for some outcomes, with small numbers of included adolescents.

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 3 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### SUMMARY OF FINDINGS FOR THE MAIN COMPARISON [Explanation]

#### Diet, physical activity and behavioural interventions for the treatment of overweight or obesity in adolescents aged 12-17 years

Patient or population: adolescents (aged 12-17 years) being overweight or obese

Settings: school; community; healthcare

Intervention: behaviour changing interventions (behavioural, diet, physical activity (or a combination) components)

Comparison: usual care; concomitant therapy; no intervention/wait list

| Outcomes  | Assumed risk  | Corresponding risk  | Relative effect | No of participants                           | Quality of the evidence  | Comments   |

<sup>*c*</sup>Downgraded one level due to inconsistency ( $I^2 = 96\%$ ); see Appendix 9.

d"A BMI z score or standard deviation score indicates how many units (of the standard deviation) a child's BMI is above or below the average BMI value for their age group and sex. For instance, a z score of 1.5 indicates that a child is 1.5 standard deviations above the average value, and a z score of -1.5 indicates a child is 1.5 standard deviations below the average value." (NOO NHS 2011).

<sup>e</sup>Downgraded one level due to reporting and other bias and limited information (small number of studies and the majority of trials had less than 80% of participants enrolled included in the analysis); see Appendix 9.

ы

f Downgraded one level due to reporting and detection bias (no blinding of participants and personnel) and inconsistency (I<sup>2</sup> = 85%); see Appendix 9). s A broadly accurate guide of how to interpret the standard mean difference (SMD) is: less than 0.40 = small, 0.40 to 0.70 = moderate, greater than 0.70 = large (Higgins 2011a).

#### BACKGROUND

The prevalence of overweight and obese children and adolescents has increased throughout the world, presenting a global public health crisis (Ng 2014; WHO 2015a). Although once considered to be a condition affecting only high-income countries, rates of paediatric overweight and obesity have started to rise dramatically in some low- to middle-income countries (Wang 2012). Using the International Obesity Task Force (IOTF) standard definition, the age-standardised prevalence of overweight and obesity in children and adolescents has increased in both high-income and lowto middle-income countries since the mid-1980s (Cole 2000). In 2013, the prevalence of overweight and obese children and adolescents in high-income countries was estimated at 23.8% (95% confidence interval (CI) 22.9 to 24.7) for boys and 22.6% (95% CI 21.7 to 23.6) for girls. In low- to middle-income countries, the prevalence was estimated as 12.9% (95% CI 12.3 to 13.5) for boys and 13.4% (95% CI 13.0 to 13.9) for girls (Ng 2014). Very young children are also affected. In 2010, de Onis 2010 used the World Health Organization (WHO) growth standards (WHO 2015b) to estimate that over 42 million children under five years of age were overweight or obese, with approximately 35 million of these children living in low- to middle-income countries.

Inequalities in overweight and obesity prevalence have also been documented. Generally, socioeconomically disadvantaged children in high-income countries (Knai 2012; Shrewsbury 2008), and children of higher socioeconomic status in low- to middle-income countries (Lobstein 2004; Wang 2012) are at greater risk of becoming overweight. However, this relationship may vary by population demographics (e.g. age, gender, ethnicity), and environment (e.g. country, urbanisation) (Wang 2012). The prevalence of obesity varies by ethnicity, with large data sets showing substantial ethnic variation in English (HSCIC 2015), US (Freedman 2006; Skinner 2014), and New Zealand (Rajput 2014) child populations.

While there is some evidence that the rate of increase in paediatric obesity may be slowing in some high-income countries, current levels remain too high, and continue to rise in many lowto middle-income countries (Olds 2011; Rokholm 2010). However, an additional concern in some high-income countries such as the USA (Kelly 2013; Skinner 2014), and England (CMO 2015; Ells 2015), is the rise in severe paediatric obesity. While the IOTF published an international definition for severe paediatric (morbid) obesity in 2012 (Cole 2012), often severe obesity prevalence is reported using country-specific cut-off points making international comparisons difficult. However, data from the USA (Skinner 2014), and England (Ells 2015), have shown that the prevalence of severe paediatric obesity varies by socioeconomic status and ethnicity, and may result in a greater risk of adverse cardiometabolic events and severe obesity in adulthood (Kelly 2013).

#### **Description of the condition**

Childhood overweight and obesity results from an accumulation of excess body fat, and can increase the risk of both short- and longer-term health consequences. Numerous obesity-related co morbidities can develop during childhood, which include muscular skeletal complaints (Paulis 2014); cardiovascular risk factors such as hypertension, insulin resistance and hyperlipidaemia (Reilly 2003), even in very young children (Bocca 2013); and conditions such as such as sleep apnoea (Narang 2012), asthma (Egan 2013), liver disease, and type 2 diabetes mellitus (Daniels 2009; Lobstein 2004). The condition can also affect psychosocial well-being, with obese young people susceptible to reduced self-esteem and health-related quality of life (Griffiths 2010), and stigmatisation (Puhl 2007; Tang-Peronard 2008). Evidence also shows that childhood obesity can track into adulthood (Parsons 1999; Singh 2008; Whitaker 1997), and is therefore associated with an increased risk of ill health later in life (Reilly 2003).

#### **Description of the intervention**

Given the serious implications associated with childhood and adolescent obesity, effective treatment is imperative. While the fundamental principles of weight management in children and adolescents are the same as in adults (i.e. reduced energy intake and increased energy expenditure), the primary aim of treatment (i.e. weight reduction or deceleration of weight gain) and the most suitable intervention approach vary, and are dependent on the child's age and degree of excess weight, among other considerations. Behaviour changing interventions combining dietary, physical activity and behavioural components are effective and are considered the current best practice in the treatment of childhood obesity in adolescents under 18 years of age (WHO 2015c).

#### Adverse effects of the intervention

It is not anticipated that diet, physical activity and behavioural interventions will lead to adverse outcomes. However, as with all obesity treatment interventions in children and young people, potential adverse effects should be considered, including effects on linear growth, eating disorders and psychological well-being.

#### How the intervention might work

The cause of childhood obesity is multifactorial, including dietary, activity, behavioural and environmental factors (Orsi 2011). Modifying these factors by behaviour changing interventions is considered the line of treatment of childhood overweight and obesity (Spear 2007). Behaviour changing interventions aim to improve dietary intake, increase activity levels, reduce sedentary behaviour, provide techniques to sustain healthy lifestyle and may have parental or family involvement (Kothandan 2014). Interventions may target one behavioural component (diet only or physical

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 7 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. activity only) while other interventions integrate several components (diet, physical activity and behavioural modification) that seem to show promising results in decreasing overweight and obesity in adolescents (Jelalian 1999). Behavioural modification is often based on theoretical elements such as cognitive behavioural theory to help adolescents sustain changes and minimise relapse (Doak 2006). Theory-based interventions address different elements such as healthy food choices, environmental control, positive thinking and goal-setting that appear to be linked to positive weight outcomes (Dewar 2013; MacDonell 2010; White 2004). Earlier systematic reviews showed that behaviour changing interventions improved weight reduction in children aged 19 and younger (Ho 2012; Wilfley 2007), while one systematic review by Kelly and colleagues showed that interventions addressing nutrition, physical activity and behavioural skills with parental involvement appears to be an effective way to reduce adolescent obesity (Kelly 2008). One systematic review by Ruotsalainen and colleagues showed that supervised physical activity interventions have a favourable effect on adolescent BMI. Ruotsalainen acknowledged the importance of complex interventions that involve behavioural modification and management in the implementation of physical activity in adolescents (Ruotsalainen 2015), while the effect of dietary interventions remains unclear. One systematic review by Collins and colleagues found inconsistent evidence on the role of dietetic interventions in the treatment of childhood obesity (Collins 2006). However, the length, delivery setting and long-term effect of behaviour changing interventions in the treatment of adolescent obesity remains unclear (Ho 2012; McGovern 2008; Wilfley 2007). The importance of behaviour changing interventions in treating childhood obesity has led to questioning their effectiveness in adolescents and whether different types of behavioural modification are more effective than others.

#### Why it is important to do this review

The first version of this systematic review was published in 2003 and included analysis of childhood obesity treatment trials published up to July 2001 (Summerbell 2003). The second version was published in 2009 providing an update to the 2003 review (Oude Luttikhuis 2009). To reflect the rapid growth in this field, the third update to this review has been split across six reviews focusing on the following treatment approaches: surgery; drugs; parent-only interventions; diet, physical activity and behavioural interventions for young children aged 0 to 6 years; school children aged 5 to 11 years and adolescents aged 12 to 17 years. The current review examines the effectiveness of interventions for adolescents aged 12 to 17 years. Previous systematic reviews identified gaps in research assessing interventions specifically for this age group (Doak 2006). Other systematic reviews did not focus on adolescents specifically (Ho 2012; Peirson 2015; Wilfley 2007) or focused on specific interventions (Ruotsalainen 2015). This review has extended the evidence base by including trials of any form of behaviour changing intervention aimed to treat obesity in adolescents aged 12 to 17 years. It also includes the effect of behaviour changing interventions on other adiposity indicators (e.g. waist circumference, body fat), behavioural change, quality of life, selfesteem and views of the intervention. The results of this current review and other systematic reviews in this series will provide information on which to underpin clinical guidelines and health policy on the treatment of childhood obesity.

#### OBJECTIVES

To assess the effects of diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years.

#### METHODS

#### Criteria for considering studies for this review

#### Types of studies

We included randomised controlled clinical trials (RCT). For cross-over trials, we only analysed the first phase before cross-over (if this was six months or more) to avoid the potential of carry over effects. Included studies observed participants for a minimum of six months (this time frame refers to the intervention itself or to a combination of the intervention with a follow-up phase).

#### **Types of participants**

We included studies of overweight or obese adolescents with a mean study age of 12 to 17 years at the commencement of the intervention. We excluded studies of critically ill people, pregnant or breastfeeding women, or adolescents with a syndromic cause for their obesity (e.g. Prader-Willi syndrome).

#### Diagnostic criteria

Any method of overweight or obesity classification was acceptable.

#### **Types of interventions**

We planned to investigate the following comparisons of intervention versus control/comparator.

#### Intervention

Any form of behaviour changing intervention with a primary aim to treat overweight or obesity. Behaviour changing interventions included any form of dietary, physical activity, behavioural therapy, or a combination of these delivered as a single or multicomponent intervention, in any setting, using any delivery method

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 8 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. and included studies which examined weight loss or maintenance or both.

#### Comparator

No treatment/wait list control, usual care or an alternative concomitant therapy providing it is delivered in the intervention arm. Concomitant interventions had to be the same in the intervention and comparator groups to establish fair comparisons.

#### Types of outcome measures

#### **Primary outcomes**

- Changes in measured BMI or body weight.
- Adverse events.

#### Secondary outcomes

- Health-related quality of life.
- Self-esteem.
- All-cause mortality.
- Morbidity.
- Anthropometric measures other than BMI.
- Behaviour change.
- Participants' views of the intervention.
- Socioeconomic effects.
- Parenting skill and relationships.

#### Method and timing of outcome measurement

• Changes in BMI (kg/m<sup>2</sup>) and body weight (kg): measured at baseline and at least at six months.

• Adverse events: defined as an adverse outcome that occurred during or after the intervention but was not necessarily caused by it, and measured at baseline and at least at six months.

• Health-related quality of life: evaluated by a validated instrument such as Paediatric Quality of Life Inventory and measured at baseline and at least at six months.

• Self-esteem: evaluated by a validated instrument such as Rosenberg Self-Esteem Scale and measured at baseline and at least at six months.

• All-cause mortality: defined as any death that occurred during or after the intervention and measured at six months or later. Morbidity: defined as illness or harm associated with the intervention and measured at baseline and six months or later.

• Anthropometric measures other than change in BMI: defined by validated tools such as waist circumference, skin-fold thickness, waist-to-hip ratio, dual x-ray absorptiometry (DXA) or bioelectrical impedance analysis and measured at baseline and at least at six months.

• Behaviour change: defined as validated measures of diet and physical activity and measured at baseline and at least at six months. Participants' views of the intervention: defined as documented accounts from participant feedback and measured at baseline and at least at six months.

• Parent-child relationship or assessment of parenting: evaluated by a validated instrument and measured at baseline and at least at six months.

• Socioeconomic effects defined as a validated measure of socioeconomic status such as parental income or educational status and measured at baseline and at least at six months.

#### 'Summary of findings' table

We presented a 'Summary of findings' table reporting the following outcomes listed according to priority.

- Changes in BMI and body weight.
- Adverse events.
- Health-related quality of life.
- All-cause mortality.
- Morbidity.
- Socioeconomic effects.

#### Search methods for identification of studies

#### **Electronic searches**

We searched the following sources from inception of each database to 14 July 2016 and placed no restrictions on the language of publication.

• Cochrane Central Register of Controlled Trials (CENTRAL) (2016, Issue 6).

• Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Ovid MEDLINE(R) Daily and Ovid MEDLINE(R) (from 1946).

- Embase Ovid (1974 to 2016 week 28).
- PsycINFO (1806 to July week 1 2016).
- CINAHL.

• LILACS (Latin American and Caribbean Health Science Information database) (last update 8 July 2016).

- ClinicalTrials.gov (www.clinicaltrials.gov).
- WHO International Clinical Trials Registry Platform (ICTRP) (www.who.int/trialsearch/).

We continuously applied a MEDLINE (via OvidSP) e-mail alert service established by the Cochrane Metabolic and Endocrine Disorders Group (CMED) to identify newly published studies using the same search strategy as described for MEDLINE (for details on search strategies and search platforms, see Appendix 1). Should we have identified new studies for inclusion, we planned to evaluate these, incorporated findings in our review and resubmitted another review draft (Beller 2013).

If we detected additional relevant key words during any of the electronic or other searches, we modified the electronic search strategies to incorporate these terms and documented the changes.

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 9 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### Searching other resources

We tried to identify other potentially eligible trials or ancillary publications by searching the reference lists of retrieved included trials, (systematic) reviews, meta-analyses and health technology assessment reports. We also contacted study authors of included trials to identify any further studies that we may have missed.

#### Data collection and analysis

#### Selection of studies

Two review authors (two of LA-K, RJ, EL, JC, KR, CO, LA, EM, LE, HF, JO) independently scanned the abstract, title, or both, of every record retrieved, to determine which studies should be assessed further. We investigated all potentially relevant articles as full text. We resolved any discrepancies through consensus or recourse to a third review author (of KR, EL, LA-K). Where resolution of a disagreement was not possible, we added the article to those 'awaiting assessment' and contacted study authors for clarification. We present an adapted PRISMA flow chart showing the process of study selection (Liberati 2009).

#### Data extraction and management

For studies that fulfilled the inclusion criteria, two review authors (of LA-K, EL, JC, RJ, CO, LA, EM, KR, HF, RV, MM, JO) independently abstracted key participant and intervention characteristics and reported data on efficacy outcomes and adverse events using standard data extraction templates as supplied by Cochrane Metabolic and Endocrine Disorders Group, with any disagreements to be resolved by discussion, or, if required, by consultation with a third review author (KR or EL) (for details, see Table 1; Appendix 2; Appendix 3; Appendix 4; Appendix 5; Appendix 6; Appendix 7; Appendix 8; Appendix 9; Appendix 10).

We provided information including trial identifier about potentially relevant ongoing studies in the Characteristics of ongoing studies table and in Appendix 5 (Matrix of study endpoints (publications and trial documents)). We tried to find the protocol of each included study and reported primary, secondary and other outcomes in comparison with data in publications in Appendix 5. We e-mailed all authors of included studies to enquire whether they were willing to answer questions regarding their trials. Appendix 10 shows the results of this survey. Thereafter, we sought relevant missing information on the trial from the primary author(s) of the article, if required.

#### Dealing with duplicate and companion publications

In the event of duplicate publications, companion documents or multiple reports of a primary study, we tried to maximise yield of information by collating all available data and use the most complete data set aggregated across all known publications. In case of doubt, we gave priority to the publication reporting the longest follow-up associated with our primary or secondary outcomes.

#### Assessment of risk of bias in included studies

We used the Cochrane 'risk of bias' assessment tool (Higgins 2011a; Higgins 2011b), and evaluated the following criteria.

- Random sequence generation (selection bias).
- Allocation concealment (selection bias).
- Imbalances in baseline characteristics.
- Blinding of participants and personnel (performance bias).
- Blinding of outcome assessment (detection bias).
- Incomplete outcome data (attrition bias).
- Selective reporting (reporting bias).
- Other potential sources of bias.

We judged the above 'Risk of bias' criteria as 'low risk', 'high risk' or 'unclear risk' and evaluated individual bias items as described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011a). We present a 'Risk of bias' graph and a 'Risk of bias summary'. We assessed the impact of individual bias domains on study results at endpoint and study levels. In case of high risk of selection bias, all endpoints investigated in the associated study were marked as 'high risk'.

We evaluated whether imbalances in baseline characteristics existed and how these were addressed (Egbewale 2014).

For performance bias (blinding of participants and personnel) and detection bias (blinding of outcome assessors) we evaluated the risk of bias separately for each outcome type (objective and subjective) (Hróbjartsson 2013). We noted whether endpoints were self-reported, investigator-assessed or adjudicated outcome measures. We considered the implications of missing outcome data from individual participants per outcome such as high dropout rates (e.g. above 15%) or disparate attrition rates (e.g. difference of 10% or more between study arms).

We assessed outcome reporting bias by integrating the results of 'Examination of outcome reporting bias' (Kirkham 2010) (Appendix 6), in the 'Matrix of study endpoints (publications and trial documents)' (Appendix 5), and 'Outcomes (outcomes reported in abstract of publication)' section of the Characteristics of included studies table. This analysis formed the basis for the judgement of selective reporting (reporting bias).

We defined the following endpoints as potentially self-reported outcomes.

- Adverse events.
- Health-related quality of life.
- Participant's views of the intervention.
- Changes in body weight.
- Self-esteem.
- Behaviour change.

We defined the following outcomes as potentially investigatorassessed outcomes.

• Changes in BMI and body weight.

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 10 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- Adverse events.
- All-cause mortality.
- Morbidity.

#### Measures of treatment effect

We expressed dichotomous data as odds ratios (ORs) or risk ratios (RRs) with 95% confidence intervals (CIs). We expressed continuous data as mean differences (MD) if they used the same instruments or standardised mean differences (SMD) if they used different instruments with 95% CI. We expressed time-to-event data as hazard ratios (HRs) with 95% CIs.

We included studies reporting multiple comparison groups in this review. Where this was the case, we considered whether the aim of the trial was to test for differences between these groups, and whether the study authors found a significant difference. Where there were no demonstrated differences, we merged groups as recommended by the *Cochrane Handbook for Systematic Reviews of Interventions* (Section 7.7.8, Higgins 2011a). In studies that found a difference between groups, we used the data for the control group for each intervention group comparison and reduced the weight assigned to the control group by dividing the number of participants in the control group by the number of intervention groups.

#### Unit of analysis issues

We used data from the first period of cross-over trials if available. We collected data from the latest available time point in the follow-up reported in the studies to avoid double-counting trials in the same analysis. For cluster RCTs, we used the denominator reported in the trial and considered how the analysis methods used took account of the effect of clustering. Due to the small number of cluster RCTs found, we decided not to adjust the data so we performed sensitivity analyses to ascertain if the results were sensitive to the inclusion of studies with a cluster design.

#### Dealing with missing data

We obtained relevant missing data from study authors, if feasible, and evaluated important numerical data such as screened, eligible, randomised participants as well as intention-to-treat (ITT), astreated and per-protocol populations. We investigated attrition rates (e.g. dropouts, losses to follow-up and withdrawals), and critically appraised issues of missing data and imputation methods (e.g. last observation carried forward (LOCF)).

Where standard deviations (SD) for outcomes were not reported, and we did not receive information from study authors, we imputed these values by assuming the SD of the missing outcome to be the same as the largest SD from those studies where this information was reported. We investigated the impact of imputation on meta-analyses by means of sensitivity analyses. Where papers did not report results as change from baseline, we calculated this and for the SD differences followed the methods presented in the *Cochrane Handbook for Systematic Reviews of Intervention* for imputing these (Section 16.1.3.2, Higgins 2011a), and assumed a correlation of 0.5 between baseline and follow-up measures as suggested by Follmann 1992.

#### Assessment of heterogeneity

In the event of substantial clinical or methodological heterogeneity, we did not report study results as meta-analytically pooled effect estimates. We identified heterogeneity by visual inspection of forest plots and by using a standard Chi<sup>2</sup> test with a significance level of  $\alpha = 0.1$ , in view of the low power of this test. We examined heterogeneity using the I<sup>2</sup> statistic, which quantifies inconsistency across studies to assess the impact of heterogeneity on the meta-analysis (Higgins 2002; Higgins 2003), where an I<sup>2</sup> statistic of 75% or more indicates a considerable level of inconsistency (Higgins 2011a).

When we found heterogeneity, we attempted to determine potential reasons for it by examining individual study and subgroup characteristics.

#### Assessment of reporting biases

If we included 10 studies or more for a given outcome, we used funnel plots to assess small-study effects. Due to several explanations for funnel plot asymmetry, we interpreted results carefully (Sterne 2011).

#### Data synthesis

Unless there is good evidence for homogeneous effects across studies we primarily summarised low risk of bias data using a randomeffects model (Wood 2008). We interpreted random-effects metaanalyses with due consideration of the whole distribution of effects, ideally by presenting a prediction interval (Higgins 2009). A prediction interval specifies a predicted range for the true treatment effect in an individual study (Riley 2011). In addition, we performed statistical analyses according to the statistical guidelines presented in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011a).

#### Quality of evidence

We presented the overall quality of the evidence for each outcome according to the GRADE approach which takes into account issues related to internal validity (risk of bias, inconsistency, imprecision, publication bias)and also to external validity, such as directness of results. Two review authors (LA-K and KR/EL) rated the quality for each outcome. We presented a summary of the evidence in a Summary of findings for the main comparison, which provides key information about the best estimate of the magnitude of the effect, in relative terms and absolute differences for each relevant comparison of alternative management strategies, numbers of participants and studies addressing each important outcome and the rating of the overall confidence in effect estimates for each

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 11 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. outcome. We created the 'Summary of findings' table based on the methods described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011a). We presented results on the outcomes as described in Types of outcome measures. If metaanalysis was not possible, we presented results in a narrative 'Summary of findings' table.

In addition, we established an appendix 'Checklist to aid consistency and reproducibility of GRADE assessments' (Meader 2014) to help with standardisation of 'Summary of findings' tables (Appendix 9).

#### Subgroup analysis and investigation of heterogeneity

We expected the following characteristics to introduce clinical heterogeneity, and planned to carry out subgroup analyses with investigation of interactions for our primary outcomes.

- Duration of follow-up.
- Duration of the intervention.
- Duration of postintervention follow-up.
- Type of comparator group.
- Mode of delivery of the intervention.
- Setting.
- Type of intervention.
- Theoretical basis to the intervention.
- Parental involvement.

#### Sensitivity analysis

We planned to perform sensitivity analyses to explore the influence of the following factors on effect size.

• Restricting the analysis to published studies, and by publication language.

• Restricting the analysis taking into account risk of bias, as specified in the section Assessment of risk of bias in included studies section.

• Restricting the analysis to studies of adolescents without specific health conditions.

• Restricting the analysis to studies with no uncertainties (such as study duration, imputed data).

We also tested the robustness of the results by repeating the analysis using different measures of effect size (RRs, ORs, etc.) and different statistical models (fixed-effect and random-effects models).

#### RESULTS

#### **Description of studies**

For a detailed description of trials, see the Characteristics of included studies, Characteristics of excluded studies, and Characteristics of ongoing studies tables.

#### **Results of the search**

This search is up to date as of July 2016 in addition to ongoing email alerts from MEDLINE. The searches generated 16,106 hits after duplicates were removed. Fifty-two additional records were identified through non-database sources. Screening of titles and abstracts identified 736 records to go forward for formal inclusion and exclusion. Forty-four completed RCTs fulfilled the inclusion criteria and were included in the review. For a detailed description of the included trials, see the Characteristics of included studies table. The search identified 50 ongoing trials, which are reported in the Characteristics of ongoing studies table. The flow of trials through the review is presented in Figure 1.

#### Figure I. Study flow diagram.

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 13 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### **Included studies**

A detailed description of the characteristics of included studies is presented elsewhere (see Characteristics of included studies and Appendix 2; Appendix 3; Appendix 4; Appendix 5; Appendix 6; Appendix 7; Appendix 8; Appendix 11). The following is a succinct overview.

#### Source of data

All data presented in the review were obtained from the published literature. We contacted all study authors for additional information and results are presented in Appendix 10.

#### Comparisons

To meet the inclusion criteria for the review comparators could be no treatment, usual care or a concomitant therapy providing it was also included in the intervention group. In nine trials the comparator was either no intervention or a wait list control (Brennan 2013; Carraway 2014; Ebbeling 2012; Luna-Pech 2014; Pakpour 2015; Patsopoulou 2017; Schranz 2014; Toulabi 2012; Vos 2011). Twenty-three studies used usual care comparators (Bean 2014; Boodai 2014; Carrel 2005; Christie 2011; Daley 2005; Debar 2012; Ebbeling 2003; Ford 2010; Gourlan 2013; Hofsteenge 2014; Jiang 2005; Kong 2013; Love-Osborne 2014; NCT00132132; NCT00807560; Patrick 2013; Pbert 2013; Pitetti 2007; Saelens 2002; Savoye 2007; Vissers 2008; Visuthranukul 2015; van Egmond-Frohlich 2006). Twelve trials used a concomitant therapy (Brownell 1983; Chandra 1968; Grey 2009; Jelalian 2016; Kong 2014; Nguyen 2012; Norman 2016; Resnicow 2005; Sigal 2014; Walpole 2013; Wengle 2011; Wong 2015).

#### Overview of trial populations

The 44 trials included 4781 participants. Approximately 2555 were randomised to an intervention and 1850 to a comparator. The proportion of participants finishing the study, where reported, ranged from 34% to 100% in the intervention groups and from 38% to 100% in the comparator groups. Individual sample size ranged from 10 to 521.

#### Study design

Thirty-nine trials were parallel comparisons with individual randomisation. Four trials were cluster RCTs (Grey 2009; Kong 2013; Pbert 2013; Resnicow 2005), and one was a cross-over trial (Brennan 2013). All 44 trials had a superiority design. Five trials had three arms (Brownell 1983; Daley 2005; Norman 2016; Pakpour 2015; Patsopoulou 2017), and two trials had four arms (Patrick 2013; Sigal 2014). The majority (24) were single centre trials, although the number of centres was unclear or not reported in 10 trials. Two trials had six centres (Grey 2009; Kong 2013), and one study each had two (Brennan 2013), eight (Pbert 2013), 10 (Resnicow 2005), 12 (Toulabi 2012), 15 (Patsopoulou 2017) or 18 (Patrick 2013) centres. Trials were performed from 1968 to 2015. The duration of the intervention ranged from six weeks to two years, and the duration of follow-up ranged from six months to two years. Eight trials had some form of run-in period prior to the start of the study (Brownell 1983; Chandra 1968; Luna-Pech 2014; Norman 2016; Pitetti 2007; Schranz 2014; Sigal 2014; Wengle 2011). None of the trials was terminated early.

#### Settings

The interventions were carried out in a variety of settings. These included in schools in nine trials (Carrel 2005; Grey 2009; Jiang 2005; Kong 2013; Love-Osborne 2014; Pbert 2013; Pitetti 2007; Toulabi 2012; Vissers 2008), in the community or home in eight trials (Ebbeling 2012; Nguyen 2012; Patrick 2013; Patsopoulou 2017; Resnicow 2005; Saelens 2002; Schranz 2014; Sigal 2014), and various healthcare settings, including outpatients, primary care, research clinics and other hospital sites in 26 trials (based on author locations where the study did not explicitly report this) (Bean 2014; Boodai 2014; Brennan 2013; Brownell 1983; Carraway 2014; Chandra 1968; Christie 2011; Daley 2005; Debar 2012; Ebbeling 2003; Ford 2010; Gourlan 2013; Hofsteenge 2014; Jelalian 2016; Kong 2014; Luna-Pech 2014; NCT00132132; NCT00807560; Norman 2016; Pakpour 2015; Savoye 2007; Visuthranukul 2015; Vos 2011; Walpole 2013; Wengle 2011; Wong 2015).

#### Participants

The diagnostic criteria for overweight and obesity differed between the trials. Twelve trials included participants with BMI on or above the 85th percentile for age and height (Bean 2014; Carraway 2014; Ebbeling 2012; Grey 2009; Jelalian 2016; Kong 2013; Love-Osborne 2014; NCT00132132; NCT00807560; Pbert 2013; Walpole 2013; Wengle 2011), nine trials used a cutoff of on or above the 95th percentile (Boodai 2014; Carrel 2005; Ebbeling 2003; Ford 2010; Kong 2014; Luna-Pech 2014; Norman 2016; Pakpour 2015; Savoye 2007), three trials used a cut-off of on or above the 90th percentile (Debar 2012; Gourlan 2013; Resnicow 2005), and two trials used a cut-off of on or above the 98th percentile (Christie 2011; Daley 2005). The remaining trials used a range of different criteria to define overweight or obesity for inclusion in the trials (Characteristics of included studies table; Appendix 3).

Thirty-four trials reported the mean BMI at baseline (Brennan 2013; Brownell 1983; Carrel 2005; Christie 2011; Debar 2012; Ebbeling 2003; Ebbeling 2012; Ford 2010; Gourlan 2013; Grey 2009; Hofsteenge 2014; Jelalian 2016; Jiang 2005; Kong 2014; Love-Osborne 2014; Luna-Pech 2014; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015; Patsopoulou 2017; Pbert 2013; Pitetti 2007; Resnicow 2005; Saelens 2002; Savoye 2007; Schranz 2014; Sigal 2014; Toulabi 2012; Vissers 2008; Visuthranukul 2015; Vos 2011; Walpole 2013; Wengle 2011) and ranged from 26 kg/m<sup>2</sup> to 37 kg/m<sup>2</sup> in all but one study

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 14 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. (Brownell 1983), which was an outlier with BMIs in the three study groups ranging from 42 kg/m<sup>2</sup> to 45.5 kg/m<sup>2</sup>. Sixteen trials reported BMI z scores (Bean 2014; Boodai 2014; Brennan 2013; Carraway 2014; Daley 2005; Love-Osborne 2014; Luna-Pech 2014; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015; Patrick 2013; Pbert 2013; Vos 2011; Walpole 2013; Wengle 2011), and these ranged across all trials between 1.8 and 3.2 with the exception of one study (Vos 2011), which had a mean BMI Standard Deviation Score (SDS) of 4.2. One study reported BMI percentile only at baseline (at 94.5%) (Kong 2013), and two trials did not report BMI measures at baseline (Chandra 1968; Gourlan 2013). Twenty trials reported on change in weight.

Thirty-seven trials reported the gender of the study participants (Bean 2014; Boodai 2014; Brennan 2013; Brownell 1983; Carrel 2005; Chandra 1968; Christie 2011; Daley 2005; Debar 2012; Ebbeling 2003; Ebbeling 2012; Ford 2010; Gourlan 2013; Grey 2009; Hofsteenge 2014; Jelalian 2016; Jiang 2005; Kong 2013; Kong 2014; Love-Osborne 2014; Luna-Pech 2014; NCT00132132; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015; Patrick 2013; Pbert 2013; Pitetti 2007; Resnicow 2005; Savoye 2007; Schranz 2014; Sigal 2014; Vissers 2008; Visuthranukul 2015; Vos 2011; Walpole 2013, and the proportion of participants who were female ranged from 33% to 77% in all cases except the trials by Debar 2012 and Resnicow 2005 where all participants were female, and Schranz 2014 where all participants were male. Four trials did not report the gender of participants at baseline (Saelens 2002; Toulabi 2012; Wengle 2011; Wong 2015). Participants ages ranged from 12 to 17.5 years in all trials that reported mean age at baseline, 11 trials did not report mean age at baseline (Brennan 2013; Brownell 1983; Chandra 1968; Christie 2011; Daley 2005; Gourlan 2013; NCT00132132; Resnicow 2005; Saelens 2002; Toulabi 2012; Wong 2015).

Nineteen trials reported ethnicity (Bean 2014; Brownell 1983; Carraway 2014; Daley 2005; Debar 2012; Ebbeling 2012; Ford 2010; Grey 2009; Hofsteenge 2014; Jelalian 2016; Kong 2013; Love-Osborne 2014; Norman 2016; Patrick 2013; Pbert 2013; Resnicow 2005; Savoye 2007; Sigal 2014; Vos 2011). Most trials reported a mixture of ethnic backgrounds for their participants as can be seen in Appendix 3, two trials reported exclusively on African-Americans (Resnicow 2005) and participants described as 'white' (Brownell 1983).

Three trials focused on participants with specific conditions, Jelalian 2016 included people with depression, Luna-Pech 2014 included people with asthma and Pitetti 2007 included people with autism living in a residential school.

#### Interventions

Thirty-four trials included interventions that were multidisciplinary (Bean 2014; Boodai 2014; Brennan 2013; Brownell 1983; Christie 2011; Daley 2005; Debar 2012; Gourlan 2013; Grey 2009; Hofsteenge 2014; Jelalian 2016; Jiang 2005; Kong 2013; Kong 2014; Love-Osborne 2014; NCT00132132; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015;

Patrick 2013; Patsopoulou 2017; Pbert 2013; Resnicow 2005; Saelens 2002; Savoye 2007; Sigal 2014; Toulabi 2012; van Egmond-Frohlich 2006; Vissers 2008; Vos 2011; Walpole 2013; Wengle 2011; Wong 2015), where the focus was on at least two components of diet, physical activity and behavioural approaches to weight management. Five trials were focused solely on dietary interventions (Ebbeling 2003; Ebbeling 2012; Ford 2010; Luna-Pech 2014; Visuthranukul 2015), and five focused solely on physical activity interventions (Carraway 2014; Carrel 2005; Chandra 1968; Pitetti 2007; Schranz 2014). Twenty-nine trials had a theoretical basis to their interventions, these included six which had a cognitive behavioural or social cognitive theoretical basis (Hofsteenge 2014; Jelalian 2016; Nguyen 2012; Norman 2016; Pbert 2013; Vos 2011), eight which used motivational interviewing approaches (Bean 2014; Brennan 2013; Christie 2011; Gourlan 2013; Love-Osborne 2014; Pakpour 2015; Resnicow 2005; Walpole 2013), and 15 that used a variety of other psychological approaches (Boodai 2014; Brownell 1983; Daley 2005; Debar 2012; Grey 2009; Jiang 2005; Kong 2013; Kong 2014; NCT00132132; Patrick 2013; Saelens 2002; Savoye 2007; Toulabi 2012; Vissers 2008; Wengle 2011). Thirteen trials did not use a behavioural approach or did not report the theoretical basis to any behavioural component of their intervention (Carrel 2005; Chandra 1968; Ebbeling 2003; Ebbeling 2012; Ford 2010; Luna-Pech 2014; NCT00807560; Patsopoulou 2017; Pitetti 2007; Schranz 2014; Sigal 2014; Visuthranukul 2015; Wong 2015). Twenty-six trials involved parents in the intervention (Bean 2014; Boodai 2014; Brennan 2013; Brownell 1983; Carraway 2014; Christie 2011; Daley 2005; Debar 2012; Ebbeling 2012; Grey 2009; Hofsteenge 2014; Jelalian 2016; Jiang 2005; Kong 2013; Kong 2014; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015; Patrick 2013; Resnicow 2005; Savoye 2007; Toulabi 2012; Visuthranukul 2015; Vos 2011; Wengle 2011). In 15 trials, there was no parental involvement (Carrel 2005; Chandra 1968; Ebbeling 2003; Ford 2010; Gourlan 2013; Love-Osborne 2014; Luna-Pech 2014; NCT00132132; Pbert 2013; Pitetti 2007; Saelens 2002; Schranz 2014; Sigal 2014; Vissers 2008; Walpole 2013), and in three trials there were two intervention groups, one which included the parent and one which did not (Brownell 1983; Pakpour 2015; Patsopoulou 2017).

Nineteen trials delivered the intervention in a group format (Boodai 2014; Brownell 1983; Carrel 2005; Christie 2011; Daley 2005; Debar 2012; Grey 2009; Hofsteenge 2014; NCT00132132; Nguyen 2012; Pakpour 2015; Patsopoulou 2017; Pitetti 2007; Resnicow 2005; Savoye 2007; Schranz 2014; Toulabi 2012; Visuthranukul 2015; Vos 2011), for specific details see Characteristics of included studies table. In 14 studies, the intervention was individually based (Bean 2014; Brennan 2013; Ebbeling 2012; Ford 2010; Gourlan 2013; Jiang 2005; Kong 2013; Kong 2014; Luna-Pech 2014; Norman 2016; Pbert 2013; Saelens 2002; Sigal 2014; Walpole 2013), and in 10 studies, there was a mixture of some group and some individual sessions, or

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 15 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. the trial did not report the mode of delivery (Carraway 2014; Chandra 1968; Ebbeling 2003; Jelalian 2016; Love-Osborne 2014; NCT00807560; Patrick 2013; Vissers 2008; Wengle 2011; Wong 2015).

The duration of the intervention was six months or less in 30 trials (Bean 2014; Boodai 2014; Brennan 2013; Brownell 1983; Carraway 2014; Chandra 1968; Christie 2011; Daley 2005; Debar 2012; Ebbeling 2003; Gourlan 2013; Grey 2009; Jelalian 2016; Kong 2013; Kong 2014; NCT00807560; Pakpour 2015; Patsopoulou 2017; Pbert 2013; Resnicow 2005; Saelens 2002; Schranz 2014; Sigal 2014; Toulabi 2012; Vissers 2008; Visuthranukul 2015; Vos 2011; Walpole 2013; Wengle 2011; Wong 2015), and greater than six months in 14 trials (Carrel 2005; Ebbeling 2012; Ford 2010; Hofsteenge 2014; Jiang 2005; Love-Osborne 2014; Luna-Pech 2014; NCT00132132; Nguyen 2012; Norman 2016; Patrick 2013; Pitetti 2007; Savoye 2007; van Egmond-Frohlich 2006).

#### Outcomes

Twenty-three trials explicitly stated a primary endpoint in the publication (Appendix 5); in 20 of these, this was a measure of body composition such as weight or BMI. In the trial by Schranz 2014, the primary outcomes were exercise self-efficacy, physical selfworth and self-esteem. In the trial by Walpole 2013, the primary outcome was self-efficacy and in Daley 2005 the primary outcome was physical self-perceptions. All except one of the included trials (Chandra 1968) reported a BMI variable as an outcome; this was BMI in 29 trials, BMI z score in 20 trials, BMI percentile in five trials (15 trials reported more than one BMI variable, Brennan 2013; Debar 2012; Hofsteenge 2014; Jiang 2005; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015; Patrick 2013; Pbert 2013; Saelens 2002; Savoye 2007; Visuthranukul 2015; Walpole 2013; Wengle 2011). Twenty trials reported weight and five trials reported rates of adverse events as described in the Effects of interventions section. Twenty-nine trials reported other anthropometric measures (Boodai 2014; Brennan 2013; Brownell 1983; Carraway 2014; Carrel 2005; Chandra 1968; Ebbeling 2003; Ebbeling 2012; Ford 2010; Grey 2009; Hofsteenge 2014; Kong 2013; Kong 2014; NCT00132132; Nguyen 2012; Norman 2016; Pakpour 2015; Patrick 2013; Patsopoulou 2017; Pbert 2013; Saelens 2002; Savoye 2007; Schranz 2014; Sigal 2014; Toulabi 2012; Vissers 2008; Vos 2011; Walpole 2013; Wengle 2011); this was percent body fat in 14 trials, trunk fat percentage in two trials, waist circumference in 16 trials, waist-to-height ratio in three trials, waist-to-hip ratio in two trials, fat mass in five trials, trunk fat mass in two trials, lean mass in three trials and percentage of overweight in two trials. Nine trials reported healthrelated quality of life (Debar 2012; Ford 2010; Hofsteenge 2014; Nguyen 2012; Luna-Pech 2014; Pakpour 2015; Patrick 2013; van Egmond-Frohlich 2006; Vos 2011). Nine trials reported self-esteem (Brennan 2013; Carraway 2014; Daley 2005; Debar 2012; Hofsteenge 2014; Nguyen 2012; Pakpour 2015; Patrick 2013; Schranz 2014). Eleven trials reported behavioural change in terms

of dietary intake (Brennan 2013; Ebbeling 2003; Ebbeling 2012; Kong 2013; Kong 2014; Pakpour 2015; Patrick 2013; Pbert 2013; Saelens 2002; Visuthranukul 2015; Wengle 2011), while four trials reported dietary behaviour (Brennan 2013; Ford 2010; Grey 2009; Pakpour 2015). Twelve trials reported behavioural change in terms of physical activity (Debar 2012; Ebbeling 2012; Gourlan 2013; Grey 2009; Jelalian 2016; Kong 2013; Kong 2014; Pakpour 2015; Pbert 2013; Saelens 2002; Sigal 2014; Wengle 2011), while three trials reported physical activity behaviour (Grey 2009; Kong 2013; Pakpour 2015). One trials reported parenting and relationships (Brennan 2013). Eight trials reported views of the intervention (Brennan 2013; Christie 2011; Debar 2012; Jelalian 2016; Nguyen 2012; Pbert 2013; Saelens 2002; Wengle 2011).

Ten trials reported outcomes at more than one time point (Debar 2012; Ebbeling 2012; Hofsteenge 2014; Jiang 2005; Nguyen 2012; Norman 2016; Patrick 2013; Resnicow 2005; Savoye 2007; Schranz 2014).

#### **Excluded studies**

We excluded 570 of 736 articles after evaluation of the publication. The main reasons for exclusion were the intervention (aim not focused on treating overweight/obesity and duration of intervention and follow-up less than six months) and study design (not an RCT). Many trials had other reasons for exclusion such as lack of relevant outcomes or the control was not no intervention/usual care or concomitant intervention as long as this was also provided in the intervention arm (for further details see Characteristics of excluded studies table, which lists the 44 studies that closely missed the inclusion criteria for this review).

#### Studies awaiting classification

Twelve studies are awaiting classification as we await clarification from the study authors. These may be included when this review is updated if they meet the inclusion criteria.

#### **Ongoing studies**

Fifty studies are ongoing or have completed but results are not available. These may be included when this review is updated if they meet the inclusion criteria.

#### **Risk of bias in included studies**

For details on risk of bias of included studies, see the Characteristics of included studies table. For an overview of review authors' judgements about each risk of bias item for individual studies and across all studies, see Figure 2 and Figure 3. Many trials did not report adequate information to assess the risk of bias and we assessed 30 trials at high risk of bias on at least one domain. We assessed 10 trials at high risk of bias on three or more domains (Daley 2005; Hofsteenge 2014; Kong 2014; Luna-Pech 2014; NCT00807560;

#### Allocation

The majority of trials provided sufficient information on random sequence generation and were judged at low risk of bias. However, most trials provided inadequate information on concealment of allocation. Twenty-two studies reported adequate random sequence generation, but only 11 of these also described adequate concealment of allocation (Boodai 2014; Christie 2011; Daley 2005; Jelalian 2016; Kong 2014; Nguyen 2012; Schranz 2014; Sigal 2014; Visuthranukul 2015; Vos 2011; Walpole 2013), and therefore have a low risk of selection bias. One trial described allocation concealment and was at high risk of bias (Patsopoulou 2017). One trial was also high risk of bias for allocation concealment (NCT00807560). The risk of selection bias was uncertain in the remaining 31 included studies.

#### Blinding

Only one study had a low risk of performance bias (subjective and objective outcomes) as participants and personnel were blinded to treatment allocation (Gourlan 2013). Nineteen studies had a high risk of performance bias for subjective and objective outcomes (Christie 2011; Daley 2005; Hofsteenge 2014; Kong 2014; Luna-Pech 2014; NCT00807560; Nguyen 2012; Pakpour 2015; Patsopoulou 2017; Pbert 2013; Schranz 2014; Sigal 2014) or objective outcomes only (subjective outcomes not reported) (Bean 2014; Boodai 2014; Carrel 2005; Debar 2012; Ford 2010; NCT00132132; Savoye 2007). The risk of performance bias was unclear in the remaining 24 studies.

The risk of detection bias was low for objective outcomes (regardless of whether outcome assessors were blinded to treatment allocation) in 44 studies. For subjective outcomes, six studies blinded outcome assessors (Brennan 2013; Gourlan 2013; Jelalian 2016; Nguyen 2012; Norman 2016; Pakpour 2015), and this was unclear in 17 studies (Carraway 2014; Christie 2011; Debar 2012; Ebbeling 2003; Ebbeling 2012; Grey 2009; Kong 2013; NCT00807560; Patrick 2013; Patsopoulou 2017; Saelens 2002; Toulabi 2012; van Egmond-Frohlich 2006; Visuthranukul 2015; Vos 2011; Wengle 2011; Wong 2015). The risk of detection bias was judged to be high in the remaining seven studies reporting subjective ouLena1234tcomes (Daley 2005; Hofsteenge 2014; Kong 2014; Luna-Pech 2014; Pbert 2013; Schranz 2014; Sigal 2014).

#### Incomplete outcome data

The risk of attrition bias was low in 17 studies (Brennan 2013; Carraway 2014; Ebbeling 2003; Ebbeling 2012; Gourlan 2013; Grey 2009; Hofsteenge 2014; Nguyen 2012; Norman 2016; Patrick 2013; Pbert 2013; Pitetti 2007; Resnicow 2005; Savoye 2007; Sigal 2014; Vos 2011; Walpole 2013). Eleven studies had a high risk of attrition bias on objective and subjective (where reported) outcome measures due to an imbalance in attrition between study groups (Carrel 2005; Jelalian 2016; Kong 2013; Kong 2014; Love-Osborne 2014; NCT00132132; NCT00807560; Saelens 2002; Schranz 2014; van Egmond-Frohlich 2006; Vissers 2008). The remaining 16 studies were at unclear risk of bias due to insufficient reporting of attrition, such as not providing reasons for missing data.

#### Selective reporting

Fourteen studies were at high risk of reporting bias (Boodai 2014; Brennan 2013; Ebbeling 2003; Ford 2010; Hofsteenge 2014; Love-Osborne 2014; NCT00807560; Norman 2016; Pbert 2013; Pitetti 2007; Schranz 2014; Sigal 2014; van Egmond-Frohlich 2006; Vos 2011). In 17 studies, this was unclear, as the study protocol or trial record were unavailable, or the trial had yet to be fully published. The remaining 13 studies reported all outcomes as stated.

#### Other potential sources of bias

There was high risk of bias in one study as the run-in programme was conducted to minimise participant attrition, but may have resulted in a more motivated sample of participants and parents compared with non-run-in trial cohorts (Norman 2016). There was an unclear risk of other sources of bias in 10 studies (Bean 2014; Boodai 2014; Brennan 2013; Carraway 2014; Grey 2009; Kong 2013; NCT00132132; NCT00807560; Pbert 2013; Wong 2015). In one of these studies, the participating churches (which were the unit of randomisation) requested that the comparison condition received a meaningful intervention, which may have had an impact on results (Resnicow 2005). The remaining 32 studies were at low risk of other sources of bias.

#### **Effects of interventions**

See: **Summary of findings for the main comparison** Diet, physical activity and behavioural interventions for the treatment of overweight or obesity in adolescents aged 12 to 17 years None of the included studies reported all-cause mortality, morbidity and socioeconomic effects.

All diet, physical activity and behavioural interventions versus controls

**Primary outcomes** 

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 19 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. Forty-four trials compared a diet, physical activity, behavioural intervention or a combination of these with usual care, no active intervention or wait list control or a concomitant therapy. Five studies assessed more than one intervention (Brownell 1983; Pakpour 2015; Patrick 2013; Patsopoulou 2017; Sigal 2014). In one three arm trial, Brownell 1983 assessed a multicomponent intervention with three different approaches; mothers attended sessions with the adolescents, mothers attended separate sessions to the adolescent or only the adolescents received the intervention. The study by Pakpour 2015 compared motivational interviewing with a passive control (no details); there were two intervention groups, one with parental involvement and one without. In the study by Patsopoulou 2017, there were two intervention groups compared to no intervention, an activity group and an activity plus diet group with parental involvement. Sigal 2014 allocated participants to four arms comparing different physical activity interventions with a diet-only control group. All groups received the dietary intervention and this was compared to a diet plus aerobic exercise intervention, a diet plus resistance training intervention and a diet plus aerobic plus resistance training intervention. The study by Patrick 2013 compared three different website interventions (website alone, website and group sessions, website and text messages) with a usual care control. There were no substantial differences in the study between the interventions and these were therefore merged into one group as described in the Measures of treatment effect section. One study provided gender stratified analyses (Norman 2016). One study had two control groups, a usual care control and an exercise placebo of body conditioning (an attention control) (Daley 2005). As there was no aim in the study to test the difference between these two control groups, and the attention control was not intended to promote weight control, we merged these two groups into one control arm for the purpose of the review. The other 37 trials each assessed different interventions as described above (Bean 2014; Boodai 2014; Brennan 2013; Carrel 2005; Chandra 1968; Christie 2011; Debar 2012; Ebbeling 2003; Ebbeling 2012; Ford 2010; Gourlan 2013; Grey 2009; Hofsteenge 2014; Jelalian 2016; Jiang 2005; Kong 2013; Kong 2014; NCT00132132; NCT00807560; Nguyen 2012; Love-Osborne 2014; Luna-Pech 2014; Norman 2016; Pbert 2013; Pitetti 2007; Resnicow 2005; Saelens 2002; Savoye 2007; Schranz 2014; Sigal 2014; Toulabi 2012; van Egmond-Frohlich 2006; Vissers 2008; Visuthranukul 2015; Vos 2011; Walpole 2013; Wengle 2011).

Outcomes are considered here at the longest point of follow-up for each study. Sensitivity analyses and subgroup analyses around these outcomes are reported below.

#### Changes in body mass index or body weight

All but one study (Chandra 1968) reported BMI variables as outcomes. Twenty-nine studies reported BMI and 20 studies reported BMI z score. Twenty-eight trials (33 comparisons) reported BMI change data that were suitable for meta-analysis. Pooling the studies in a random-effects meta-analysis demonstrated a reduction in BMI in the intervention groups compared with control groups at the longest point of follow-up (MD -1.18 kg/m<sup>2</sup> (95% CI -1.67 to -0.69); P < 0.00001; 2774 participants; 28 studies; 34 comparisons; low quality evidence; Analysis 1.1).

Meta-analysis of BMI z score at the longest point of follow-up showed a reduction in the intervention groups compared with the control groups (MD -0.13 units (95% CI -0.21 to -0.05); P = 0.002; 2399 participants; 20 studies; low quality evidence; Analysis 1.2).

Five studies did not report BMI or BMI z score outcomes in a format that was suitable for meta-analysis (Carraway 2014; Christie 2011; Love-Osborne 2014; Walpole 2013; Wong 2015). The study by Walpole 2013 reported median BMI and BMI z scores and the study reported no substantial differences between groups. In the study by Wong 2015, the mean BMI z score did not substantially differ between groups. Christie 2011 reported the effect estimate for BMI at six months, which was not substantially different between groups. The study by Love-Osborne 2014 reported the proportion of participants with increases or decreases in BMI z scores at different thresholds. The only relevant result was that a higher proportion of participants in the control group decreased their BMI z score by at least 0.1 compared with the intervention group. One study has not currently reported BMI outcomes having only recently published secondary outcomes (Bean 2014). The study by Carraway 2014 did not present BMI data for a mentorled exercise programme compared with wait list control.

Five studies reported BMI percentiles (Bean 2014; Brennan 2013; Debar 2012; Kong 2013; Patrick 2013). Analysis 1.3 shows results from four studies (Brennan 2013; Debar 2012; NCT00807560; Patrick 2013). The results favoured the interventions in two studies. In one study, where three interventions were combined, there was a reduction in the BMI percentile in the control group (Patrick 2013). Kong 2013 reported the median BMI percentile. This reduced in the intervention group and increased in the control group (P = 0.04). Bean 2014 did not report data.

Twenty studies (24 comparisons) reported weight change and were pooled in a random-effects meta-analysis which demonstrated a reduction in weight in the intervention groups compared with controls at the longest point of follow-up (MD -3.67 kg (95% CI -5.21 to -2.13); P < 0.00001; 1993 participants; 20 studies; moderate quality evidence; Analysis 1.4).

#### Adverse events

Five trials reported rates of adverse events (Ebbeling 2012; Ford 2010; NCT00132132; NCT00807560; Sigal 2014). There were no adverse events reported in either group in the studies by Ford 2010; NCT00132132; and NCT00807560. In the study by Ebbeling 2012, 6.4% of participants experienced an adverse event in the intervention group (no details); it was not reported

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 20 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. whether adverse events occurred in the comparator group. Sigal 2014 reported the proportions of participants experiencing adverse events, the proportion withdrawing owing to adverse events and detailed the specific adverse events in each of their four groups (see Appendix 8 for details). Adverse events were experienced in 25% of participants in the diet plus aerobic exercise group; 19% in the diet plus resistance training group; 21% in the diet plus aerobic plus resistance training group and 24% in the diet-only group.

#### Secondary outcomes

#### Anthropometric measures other than body mass index

Twenty-eight trials reported anthropometric measures other than BMI using objective measures (Boodai 2014; Brownell 1983; Brennan 2013; Carrel 2005; Ebbeling 2003; Ebbeling 2012; Ford 2010; Grey 2009; Hofsteenge 2014; Kong 2013; Kong 2014; NCT00132132; NCT00807560; Nguyen 2012; Norman 2016; Pakpour 2015; Patrick 2013; Patsopoulou 2017; Pbert 2013; Saelens 2002; Savoye 2007; Schranz 2014; Sigal 2014; Toulabi 2012; Vissers 2008; Vos 2011; Walpole 2013; Wengle 2011). Fourteen studies reported percentage of body fat change that was suitable for meta-analysis. Meta-analysis demonstrated a reduction in percentage of body fat in the intervention group compared with the control group at the longest follow-up points (MD -1.08% (95% CI -1.69 to -0.46); P = 0.0006; 1886 participants; 14 studies; Analysis 3.1). Three studies reported other measures of body fat that included percentage of fat (Carraway 2014; Pakpour 2015), and percentage of body fat-SDS (Ford 2010). All three studies found a reduction in body fat in the intervention group compared to the control group (see Table 2 for details).

Two trials reported data for percentage of trunk fat that was suitable for meta-analysis. Random-effects meta-analysis showed an MD of -0.84% ((95% CI -3.10 to 1.43); P = 0.47; 123 participants; 2 trials; Analysis 3.2).

Seventeen trials reported data for waist circumference that was suitable for meta-analysis. Random-effects meta-analysis demonstrated a reduction in waist circumference in the intervention group compared with the control group at the longest follow-up points (MD -2.26 cm (95% CI -3.80 to -0.72); P = 0.004; 1997 participants; 17 trials; Analysis 3.3). Two studies reported other measures of abdominal adiposity (Kong 2014; Vos 2011). Percentage of visceral fat did not change in either the intervention or control group (Kong 2013). One study found that both waist circumference minus SDS and waist-to-height ratio significantly decreased in the intervention arm compared to the control arm (Vos 2011) (see Table 2 for details).

Pooling three trials in a random-effects meta-analysis showed no substantial reduction in waist-to-height ratio in the intervention group compared to control group at the longest follow-up points (MD 0 (95% CI -0.02 to 0.02); P = 0.98; 276 participants; 3 trials; Analysis 3.4). Waist-to-hip ratio did not substantially reduce in the intervention group compared to the control group (MD 0.01 (95% CI -0.01 to 0.03); P = 0.22; 211 participants; 2 trials; Analysis 3.5). In one study, hip circumference seemed to decrease in the intervention group compared to the control group (Toulabi 2012; see Table 2).

Five trials reported data for fat mass that was suitable for meta-analysis. Pooling the studies in a random-effects meta-analysis demonstrated a reduction in fat mass in the intervention group compared to the control group at the longest follow-up points (MD -3.13 kg (95% CI -4.70 to -1.56); P < 0.0001; 673 participants; 5 trials; Analysis 3.6). The study by Schranz 2014 found no substantial difference for the reduction in body mass between the intervention and control groups (see Table 2 for details).

Two trials reported data for trunk fat mass that was suitable for meta-analysis. Random-effects meta-analyses showed no substantial reduction in trunk fat mass in the intervention group compared to the control group (MD -0.94 kg (95% CI -2.49 to 0.61); P = 0.24; 184 participants; 2 trials; Analysis 3.7).

Three trials reported data for lean mass that was suitable for metaanalysis. Random-effects meta-analysis showed no substantial increase in body lean mass in the intervention group compared to the control group (MD -0.21 kg (95% CI -0.88 to 0.47); P = 0.55; 417 participants; 3 trials; Analysis 3.8). The Brennan 2013 trial found that participants in the intervention group had lower truncal lean mass compared to the control group, however, statistical significance was not reported (see Table 2 for details).

Two trials reported data for percentage of overweight that was suitable for meta-analysis. Random-effects meta-analysis showed no substantial difference in the percentage of overweight between the intervention group and control group (MD -5.55% (95% CI -13.67 to 2.57); P = 0.18; 73 participants; 2 trials; Analysis 3.9). One study reported percentage of BMI reduction and found that 75% of participants in the intervention group reduced their BMI compared to 23% of participants in the control group (NCT00132132). In one trial, percentage of overweight reduced in both intervention and control at seven months' follow-up (Carraway 2014; see Table 2 for details). In one study, percentage of boys over the median BMI was lower in the intervention group compared to boys in the control group (Norman 2016). In an earlier study, average weight loss was not lower in the intervention group compared to the control (Chandra 1968; see Table 2).

#### Health-related quality of life and self-esteem

Thirteen trials reported health-related quality of life and self-esteem using validated self-reported tools (Brennan 2013; Carraway 2014; Daley 2005; Debar 2012; Ford 2010; Hofsteenge 2014; Luna-Pech 2014; Nguyen 2012; Patrick 2013; Pakpour 2015; Schranz 2014; van Egmond-Frohlich 2006; Vos 2011). Seven trials reported data for health-related quality of life change that was

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 21 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. suitable for meta-analysis. Random-effects meta-analysis demonstrated an improvement in health-related quality of life in the intervention group compared with the control group at the longest follow-up points ((SMD 0.44 (95% CI 0.09 to 0.79); P = 0.01; 972 participants; 7 studies; low quality evidence Analysis 4.1). An SD of 0.44 represents a moderate difference between groups (Higgins 2011a). The study by Ford 2010 reported narrative findings of health-related quality of life that improved in both the intervention and control arms but did not reach statistical significance (see Table 3 for further details).

Six trials reported data for self-esteem change that was suitable for meta-analysis. Random-effects meta-analysis demonstrated no substantial improvement in self-esteem for either group at the longest follow-up points (SMD 0.09 (95% CI -0.08 to 0.27; P = 0.30, 613 participants; 6 trials; Analysis 4.3). Four trials reported other measures of self-esteem and found no substantial improvement in either group for body appearance, weight satisfaction, body attribution (Hofsteenge 2014), weight efficacy (Pakpour 2015), and physical self-worth (Schranz 2014; van Egmond-Frohlich 2006). One trial reported improvement in global self-esteem post intervention and at seven months' followup for both intervention and control (Carraway 2014) (see Table 3 for further details).

#### All-cause mortality

None of the studies reported all-cause mortality.

#### Morbidity

None of the studies reported morbidity.

#### Behavioural change

#### Dietary intake

Six trials (454 participants) reported macronutrient and glycaemic consumption assessed by either food record or 24-hour dietary recall (Ebbeling 2003; Ebbeling 2012; Kong 2014; Pbert 2013; Saelens 2002; Visuthranukul 2015). Monitored intakes included fat, protein, carbohydrates, sugar, fibre, glycaemic load and glycaemic index.

Three trials reported fat intake as percentage of total energy intake for 132 participants (Ebbeling 2003; Pbert 2013; Saelens 2002). There was no substantial reduction in fat intake in either group in the studies by Pbert 2013 and Saelens 2002. In the study by Ebbeling 2003, fat intake significantly decreased in the control group but increased in the intervention group at 12 months (see Table 4 for details).

Two trials reported protein intake as percentage of total energy intake for 75 participants (Ebbeling 2003; Kong 2014). At 12

months, there was no substantial increase in protein intake in the either group in the study by Ebbeling 2003. In the study by Kong 2014 the intervention group increased protein consumption compared to the control group at six months (see Table 4 for details). The same trials (Ebbeling 2003; Kong 2014) reported carbohydrate intake. There was no substantial change in carbohydrate consumption in either the intervention or control group at six and 12 months (see Table 4 for details).

Two trials reported total sugar intake for 291 participants ( Ebbeling 2012; Pbert 2013). Participants in the intervention group reported lower intakes compared to the control group in both studies (Ebbeling 2012; Pbert 2013). See Table 4 for details. Two trials reported fibre intake for 75 participants (Ebbeling 2003; Kong 2014). At 12 months, fibre intake did not change substantially in either the intervention or control group in one study (Ebbeling 2003). The second study reported an increase in fibre consumption in the intervention group compared to the control group (Kong 2014). See Table 4 for details.

Three trials reported glycaemic load intake for 157 participants (Ebbeling 2003; Kong 2014; Pbert 2013). Glycaemic load decreased in the intervention group in two studies (Ebbeling 2003; Pbert 2013), but there was no substantial difference between the intervention and control groups in one study (Kong 2014). See Table 4 for details.

Three trials reported glycaemic index intake for 127 participants (Ebbeling 2003; Kong 2014; Visuthranukul 2015). Glycaemic index did not change in either group in the studies by Ebbeling 2003 and Kong 2014. At six months, the intervention group (25 participants) reported a higher consumption of low glycaemic index foods compared to the control group (27 participants) in one study (Visuthranukul 2015). See Table 4 for details.

Five trials (650 participants) reported fruit and vegetable intake (Brennan 2013; Kong 2013; Pakpour 2015; Patrick 2013; Wengle 2011), while two trials (408 participants) reported vegetable intake (Brennan 2013; Pakpour 2015). Dietary consumption was assessed using the Fat, Fruit and Vegetable Diet Questionnaire (FFVDQ), diet record or dietary questions from the Center for Disease Control Youth Risk Behavior System (YRBS). In all studies, except for one (Pakpour 2015), fruit and vegetable consumption did not substantially increase. In the study by Pakpour 2015, the motivational interviewing and parental involvement group had a significantly higher intake of fruit servings compared to the control group. See Table 4 for details.

Four trials (668 participants) reported beverage consumption (juice, milk and sugar-sweetened drinks) assessed by either dietary questions YRBS, 24-hour dietary recall or Food Frequency Questionnaire (FFQ) (Brennan 2013; Ebbeling 2012; Kong 2013; Pakpour 2015). Juice and milk consumption did not change substantially in either the intervention and control group in three trials (Brennan 2013; Ebbeling 2012; Pakpour 2015). Reports on sugar-sweetened drinks (606 participants) were significantly lower in the intervention group compared to the control group (Ebbeling

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 22 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. 2012; Kong 2013; Pakpour 2015). See Table 4 for details.

Five trials (742 participants) reported several dietary findings assessed by the FFQ, 24-hour dietary recall or the food record (Brennan 2013; Ebbeling 2012; Pakpour 2015; Pbert 2013; Wengle 2011) (see Table 4 for details). The consumption of fatty food items generally decreased in the intervention group compared to the control group (Pakpour 2015; Wengle 2011). There was no substantial difference between the intervention and control groups in healthier dietary consumption such as increasing salad intake and reducing added sugar (Brennan 2013; Pbert 2013). However, whole-grain intake (Wengle 2011) and unsweetened beverage consumption (Ebbeling 2012) were higher in the intervention group compared to the control group.

#### Dietary behaviour

Four trials (674 participants) reported changes in dietary behaviours assessed by either objective (e.g. Mandometer) or validated self-reported questionnaires (e.g. FFVDQ) (Brennan 2013; Ford 2010; Grey 2009; Pakpour 2015). Eating behaviours such as eating speed and usual food choices did not change substantially in either group in studies by Grey 2009 and Ford 2010. Dietary self-efficacy improved in the intervention group (118 participants) but not in the control group in one study (Pakpour 2015), while there was no change in either group (198 participants) in another study (Grey 2009). Dietary behaviour in relation to fat intake did not improve in either the intervention or control group (Brennan 2013). See Table 5 for details.

#### Physical activity

Thirteen trials (1376 participants) reported several measures of physical activity assessed using objective tools (Jelalian 2016; Kong 2013; Pbert 2013; Sigal 2014; Wengle 2011), or validated selfreported tools (Debar 2012; Ebbeling 2012; Grey 2009; Gourlan 2013; Kong 2014; Pakpour 2015; Saelens 2002; Sigal 2014). Three trials reported data for mild-to-vigorous physical activity that was suitable for meta-analysis (Kong 2013; Pbert 2013; Wengle 2011), while the study by Jelalian 2016 could not be metaanalysed (Table 6). Random-effects meta-analysis demonstrated no substantial improvement in mild-to-vigorous physical activity (MD 0.39 (95% CI -15.07 to 15.85); P = 0.96; 129 participants; 3 trials; Analysis 5.1). Two trials reported data for activity length (hours per day) that was suitable for meta-analysis (Gourlan 2013; Pakpour 2015). Random-effects meta-analysis showed no substantial improvement in activity length (MD -0.11 hours/day (95% CI -0.98 to 0.75); P = 0.80; 129 participants; 2 trials; Analysis 5.2). Only two trials reported screen time (hours per day) that was suitable for meta-analysis (Ebbeling 2012; Wengle 2011). Random-effects meta-analysis showed a favourable effect for the intervention group compared with the control group at the longest

follow-up points (MD -0.60 hours/day (95% CI -0.65 to -0.55); P < 0.00001; 241 participants; 2 trials; Analysis 5.3).

Overall, physical activity from validated self-reported measures did not substantially improve in either the intervention or control groups for increasing number of steps per day (Sigal 2014; Wengle 2011), amount per day (Debar 2012; Saelens 2002), intensity (Kong 2013), and metabolic equivalent for self-reported physical activity (Debar 2012; Ebbeling 2012; Grey 2009; Kong 2014). See Table 6 for details.

#### Physical activity behaviour

Three trials (566 participants) reported behavioural change in relation to physical activity assessed by self-reported measures (Grey 2009; Kong 2013; Pakpour 2015), or objective measures (Jelalian 2016). There was no substantial reduction in the hours spent viewing television for either the intervention or control groups in one trial (Kong 2013), while one trial showed a decrease in hours spent in sedentary behaviour in the intervention arm (Jelalian 2016). Two studies reported improvement in physical activity self-efficacy in the intervention group at 12 months (Grey 2009; Pakpour 2015). See Table 7 for details.

#### Participants' views of the intervention

Eight trials reported participants' views of the multidisciplinary intervention (Brennan 2013; Christie 2011; Debar 2012; Jelalian 2016; Nguyen 2012; Pbert 2013; Saelens 2002; Wengle 2011). Participants reported high levels of satisfaction for the components (Jelalian 2016; Nguyen 2012; Saelens 2002), services (Debar 2012), and overall quality (Brennan 2013) of multidisciplinary interventions. Similarly, participants were satisfied with the person delivering the intervention whether it was a nurse (Debar 2012), mentor (Pbert 2013; Wengle 2011), or clinician (Brennan 2013). Overall, participants thought that a multidisciplinary weight-related programme met their needs (Debar 2012), and in terms of comfort in discussing their behaviour (Pbert 2013), and ability to focus and deal with their concerns (Brennan 2013), and helped them to make behavioural changes (Christie 2011; Nguyen 2012). See Table 8 for details.

#### Socioeconomic effects

None of the studies reported socioeconomic effects.

#### Parenting and relationships

Only one trial reported parent-adolescent communication ( Brennan 2013). There was no substantial difference between adolescents in the intervention and control groups for parent-adolescent negative, problematic and supportive communication measures (see Table 9). However, participants in the intervention group reported higher positive communication with parents compared to the control group (Brennan 2013).

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 23 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### Subgroup analyses

We performed a number of subgroup analyses to test the effects of different durations of follow-up, duration of the interventions, different types of comparators, mode of delivery of the intervention, setting, type of intervention, psychological basis for the interventions and involvement of parents on the outcomes of BMI and BMI z score.

For duration of follow-up, the studies were divided into three subgroups, six months' follow-up, 12 months' follow-up and 18 months' follow-up or more. Some studies reported follow-up at more than one time point and are included in the analyses. There were no subgroup differences regarding duration of follow-up (Analysis 2.1; Analysis 6.1; Analysis 6.2). For change in BMI score (Analysis 2.2), combining studies with a duration of the intervention of six months or less and studies with a duration of the intervention of greater than six months indicated a statistically significant subgroup difference (P = 0.02).

Studies were furthermore divided by whether they had a period of postintervention follow-up (defined as the period after the active intervention and up to the final measurement) and the duration of that period: no postintervention follow-up, less than six months, six months to less than 12 months and postintervention follow-up lasting 12 months or longer. The duration of no postintervention follow-up was calculated by subtracting the active intervention and all follow-up duration). There were no subgroup differences for BMI (Analysis 7.1). For BMI z score, there was a statistically significant subgroup difference (P = 0.007). The effect size for BMI z score appeared greater in studies with a postintervention follow-up lasting 12 months or longer (Analysis 7.2).

When outcomes from studies with comparators described as no intervention or wait list control, usual care or a concomitant therapy were combined, the effect sizes for BMI change appeared larger for studies with no intervention or wait list control comparators and for studies with usual care controls (P = 0.008; Analysis 8.1). Studies were divided into three groups to test the effect of the mode of delivery of the intervention: group, individual and group plus individual delivery. There were no subgroup differences (Analysis 9.1; Analysis 9.2).

For setting, the studies were divided into three subgroups, school, community and healthcare settings. There were no subgroup differences (Analysis 10.1; Analysis 10.2).

The majority of studies were multidisciplinary interventions; however, some studies focused on diet alone or physical activity interventions alone. There were no subgroup differences (Analysis 11.1; Analysis 11.2).

Studies were categorised into four groups according to any theoretical basis for the intervention. These were those applying cognitive behavioural techniques, those applying motivational interviewing techniques, those reporting any other psychological technique and those not reporting any theoretical basis to the intervention or no psychological component to the intervention (BMI: Analysis 12.1; BMI z score: Analysis 12.2). For BMI change, there was a subgroup difference (P = 0.09).

A number of studies involved parents in their interventions while others did not explicitly provide any intervention to parents. There were no subgroup differences (Analysis 13.1; Analysis 13.2).

We performed subgroups analyses to test the effects of different tools of self-reported measures and different outcomes reported. For health-related quality of life, studies were divided into two subgroups, studies using the Pediatric Quality of Life (PedsQL) tool and studies using other self-reported tools. There were no subgroup differences (Analysis 4.4).

Studies measuring self-esteem were divided into two subgroups, studies measuring total self-esteem and studies measuring global self-worth. There were no subgroup differences (Analysis 4.4; Analysis 4.5).

Results of the subgroup analyses should be interpreted with caution given the large number of variable that we assessed.

#### Sensitivity analyses

We did not perform sensitivity analysis restricting to published studies as all included studies were published. We did not perform sensitivity analysis restricting studies to type of funding as there was no industrial funding influence. We performed sensitivity analyses for the following factors: longest follow-up with 20% or less attrition; longest follow-up with 30% or less attrition; language of publication; study design; removal of one trial specifically aimed at adolescents with severe autism (Pitetti 2007); removal of one trial specifically aimed at overweight adolescents with asthma (Luna-Pech 2014); removal of one trial specifically aimed at overweight or obese adolescents with depression (Jelalian 2016); removal of one trial where there was some uncertainty over the duration of follow-up and no response was received to a request for clarification from the authors (Toulabi 2012), and removal of one study where SDs were imputed from other studies (Pitetti 2007). These sensitivity analyses were undertaken on both the BMI and BMI z score meta-analyses as appropriate to each study.

For the sensitivity analysis testing the effect of attrition, results did not differ between comparisons for either sensitivity analyses when compared with the main summary effects for studies with 20% or less attrition at the longest follow-up: BMI (MD -1.34 kg/m<sup>2</sup> (95% CI -2.05 to -0.63); P = 0.0002; 1486 participants; 15 studies; 18 comparisons); BMI z score (MD -0.22 (95% CI -0.39 to -0.05); P = 0.01; 951 participants; 11 studies; 11 comparisons) and for studies with 30% or less attrition at the longest follow-up: BMI (MD -1.07 kg/m<sup>2</sup> (95% CI -1.62 to -0.51); P = 0.0002; 2135 participants; 20 studies; 25 comparisons); BMI z score (MD -0.18 (95% CI -0.32 to -0.05); P = 0.008; 1066 participants; 13 studies; 13 comparisons). Heterogeneity for these sensitivity analyses did not vary consistently when compared with the heterogeneity seen in the main analyses (20% or less attrition: BMI: I<sup>2</sup> = 72%; BMI z score: I<sup>2</sup> = 91%; 30% or less attrition: BMI: I<sup>2</sup> = 77%; BMI z

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 24 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. score:  $I^2 = 90\%$ ). Therefore, we included all studies regardless of rates of attrition in the analyses and subgroup.

Sensitivity analyses on the primary analyses for BMI and BMI z score removing individual trials did not have a considerable impact on the results and these trials were retained in the analyses. The removal of the study by van Egmond-Frohlich 2006 (published in German) slightly increased the BMI z score (MD -0.14 (95% CI -0.23 to -0.05); P = 0.002; 1878 participants; 19 studies; 21 comparisons), but heterogeneity remained the same ( $I^2 = 86\%$ ). The removal of the study by Pitetti 2007 from the BMI analysis did not change the MD or the CIs (MD -1.18 (95% CI -1.67 to -0.69); P < 0.00001; 2764 participants; 27 studies; 33 comparisons). The removal of the study by Jelalian 2016 changed BMI MD and CIs by one second decimal point only (MD -1.17 kg/m<sup>2</sup> (95% CI -1.66 to -0.68); P < 0.00001; 2750 participants; 27 studies; 33 studies). The removal of the study by Toulabi 2012 reduced the MD in BMI slightly and narrowed the CIs slightly (MD -1.15 kg/m<sup>2</sup> (95% CI -1.66 to -0.64); P < 0.0001; 2622 participants; 27 studies; 33 comparisons) but the result remained statistically significant with heterogeneity of  $I^2 = 78\%$ . Removing the study by Luna-Pech 2014 from the BMI z score meta-analysis reduced the MD slightly and narrowed the CIs slightly (MD -0.11 (95%

CI -0.19 to -0.03); P = 0.006; 2348 participants; 19 studies; 21 comparisons) but the result remained statistically significant and only reduced the heterogeneity slightly to  $I^2$  = 83%. One study did not report measures of variance for the BMI z score (Jiang 2005), and we imputed the SDs from another study. Removing this study from the meta-analysis reduced the effect size and reduced the 95% CIs; however, the direction of effect remained the same (MD -0.08 (95% CI -0.14 to -0.02); P = 0.007; 2331 participants; 19 studies; 21 comparisons) and reduced heterogeneity but remained considerable ( $I^2$  = 70%).

The removal of cluster RCTs where it was unclear if the effect of clustering had been taken account of in the analysis (Grey 2009; Pbert 2013) from the BMI analysis increased the MD (MD -1.34 (95% CI -1.80 to -0.89); P < 0.00001; 26 studies; 32 comparisons; 2494 participants) but heterogeneity remained highly significant ( $I^2 = 71\%$ ).

#### Assessment of reporting bias

We generated a funnel plot for the primary outcome of BMI as this analysis included the highest number of studies on which to assess publication bias. Inspection of the funnel plot suggested the possibility of a small-study bias (Figure 4).

#### Figure 4. Funnel plot of comparison: I Interventions (all) versus controls, longest follow-up, outcome: I.I BMI change (kg/m&supStart;2&supEnd;)

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 25 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### **Ongoing studies**

We found 50 ongoing RCTs (see Characteristics of ongoing studies table). Forty-four of these RCTs are parallel trials, two are cluster trials, two are cross-over trials, one is a factorial trial and in one the design is unclear. Eight trials are three-arm trials and one is a fourarm trial. The ages of the participants in these trials incorporate the range of five to 18 years in 43 trials and are not clearly reported in seven trials. In one trial, the target population is classed as overweight according to Cole international cut-offs for child obesity, in 22 trials the target population are children classed as obese (using different methods), in 23 trials the population is described as overweight or obese and in four trials the classification is unclear. Six trials include a physical activity intervention, four trials include a nutritional intervention, three trials include dietary supplements, 19 trials include a behavioural intervention and 21 trials include a multicomponent intervention.

Thirty-four trials compare the intervention to usual care or no intervention, 12 compare to a concomitant therapy also delivered in the intervention arm, one trial compares to wait list control, two trials compare the intervention to placebo and in one trial the control is not clearly defined.

BMI was the primary outcome (BMI, BMI z score, BMI-SDS, BMI percentile) in 36 trials and secondary outcome in five trials. Weight change ass the primary outcome in four trials and the secondary outcome in one trial. Two trials did not state if weight change was the primary or secondary outcome and body composition (unclear what parameters) are the secondary outcome in one trial and other outcome in one trial. The estimated study completion dates, where reported, range from March 2011 to December 2021.

#### DISCUSSION

#### Summary of main results

This systematic review summarised 44 RCTs examining the effect of behaviour changing interventions for treating overweight and obesity in adolescents aged 12 to 17 years. We only included trials with at least a six-month outcome assessment with the aim of assessing the longer-term effects of these types of interventions. Interventions and comparators varied between the included trials. Outcomes assessed also varied between groups; although all trials reported a measure of body weight, the most commonly reported measures were BMI and BMI z score. To allow comparisons across trials, we analysed outcome data at the longest follow-up period. Many trials did not report adequate information to assess the risk of bias and 27 trials were at high risk of bias on at least one domain. Overall, behaviour changing interventions were more successful than the comparators in reducing BMI (low quality evidence), BMI z score (low quality evidence) and weight (moderate quality evidence) in overweight and or obese adolescents. The effects of behaviour changing interventions were maintained at 18 to 24 months' follow-up for both BMI and BMI z score.

There were subgroup differences showing larger effects for both BMI and BMI z score where comparison groups were described as no intervention/wait list control or usual care compared to those testing concomitant interventions delivered to both the intervention and control group (P = 0.008). There were no subgroup differences between interventions with and without parental involvement or by intervention type or setting (health care, community, school) or mode of delivery (individual versus group).

Adverse events were reported in only five trials (low quality evidence). Minor adverse events occurred in one four-arm study, but there were no details in the others.

Secondary outcomes were reported less consistently across trials. Overall, behaviour changing interventions were more successful than the comparators in reducing percentage of body fat, waist circumference and total fat mass. Fewer trials measured quality of life and self-esteem. Behaviour changing interventions improved quality of life at the longest follow-up period (low quality evidence) but not self-esteem.

Overall, trials measuring physical activity showed no improvement for objective and self-reported activity although evidence was limited. However, two trials reported improvement in physical activity self-efficacy at 12 months. Dietary intakes were inconsistently measured and reported across trials, and trials used different tools to assess dietary intake and reported outcomes using different units of measure. The majority of trials reported no substantial effect of behaviour changing interventions on dietary intake although again evidence was limited.

## Overall completeness and applicability of evidence

This review identified 44 completed trials and 50 ongoing trials assessing the effect of diet, physical activity and behavioural interventions at six months or longer. The review included studies conducted in the US, Europe, Asia and the Middle East including participants of different ethnicity. Most trials included both genders except for two trials that were restricted to females and one trial was restricted to males. Over half of the trials followed the percentile range to diagnose overweight or obesity. The majority of interventions had a multidisciplinary approach which included

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 26 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. a combination of behavioural, dietary and physical activity components. Most trials reported details of the intervention that were mainly carried out for six months or less. The theoretical approach behind the intervention varied across studies with five studies using only the cognitive behavioural approach and four studies using only motivational interviewing. The majority of studies used either a mixture or other psychological theories (e.g. social cognitive theory, social learning theory, theory of planned behaviour) or did not have a theoretical approach behind the intervention. Only five trials used a mixed delivery approach (both individual and group mode) while the majority used either an individual or group delivery mode of the intervention. Studies were mainly conducted in healthcare settings while fewer trials were conducted in schools. All 44 trials reported measures of body weight but BMI and BMI z score were the commonly assessed outcomes. Adverse events were only reported in five trials and only one trial provided sufficient details of adverse events. Reports on quality of life, self-esteem, diet, physical activity, views of the intervention, and parenting and relationships were less consistent across trials. There was heterogeneity in measurement tools, assessed outcomes and unit of outcome measures. The duration of follow-up varied across trials with most trials reporting outcomes at six to nine months and fewer trials reporting outcomes at two years. Overall, behaviour changing interventions have a favourable effect on measures of body weight including BMI, BMI z score and weight change in adolescents. We found no results for our outcomes of morbidity, mortality or socioeconomic effects of intervention.

#### Quality of the evidence

We rated the quality of evidence for the outcomes of interest in this review as low with the exception of weight which was moderate (Summary of findings for the main comparison). We judged the risk of bias for many individual studies to be unclear or high for a number of domains, but we found the impact of bias on the results for BMI and weight outcomes to be limited due to the influence of low risk of bias studies in the analysis. For some outcomes where studies had high loss to follow-up, we saw a bigger effect size in sensitivity analyses. Anthropometric measures (BMI, BMI z score, weight) were downgraded for inconsistency (some variation in point estimates, poor overlap of CIs, significant statistical heterogeneity). Both BMI outcomes were downgraded further for indirectness due to the surrogacy of outcome measures (BMI and BMI z score). We maintained our decision to downgrade BMI outcomes for inconsistency even though we had some evidence that variation in effect could be explained by use of active controls in some studies. Within subgroup analysis heterogeneity remained high, indicating that there may be factors in addition to type of control intervention which give a credible explanation for inconsistency of effects across these outcomes.

Adverse events were downgraded due to risk of bias (inconsistency in reporting of data, reporting bias and attrition bias). Health-related quality of life was downgraded for risk of bias (lack of blinding of outcome assessors) and inconsistency (variability in point estimates, overlap in CI and significant statistical heterogeneity). Therefore, results should be interpreted with caution.

#### Potential biases in the review process

We included four cluster randomised trials in this review but did not adjusted the data to account for the unit of randomisation due to their limited influence on the review findings. While our approach risks introducing a unit of analysis error, the impact of this decision was questionable for the outcomes affected. Most information in our review came from studies which randomised participants rather than clusters. Sensitivity analyses restricted to individually randomised trials provided some indirect evidence that supported our approach. Given that the removal of cluster trials did not change the results, calculating effective sample sizes would reduce their weight in the analysis. Therefore, it is unlikely that the nature of the results would alter with less weight accorded to the cluster trials.

The large number of subgroup analyses in our review carries inherent risks of multiplicity and the statistically significant results for subgroup analyses we have found could simply reflect a chance finding. This should be borne in mind when considering the applicability of the results to decision-making. We conducted several other sensitivity analyses and found no significant differences. Where data of relevance were missing, either to allow assessment of eligibility, or at the data extraction stage and assessment of bias, we contacted the study authors for further information. Twelve trials are awaiting classification as information is currently unavailable to the review.

## Agreements and disagreements with other studies or reviews

The UK National Institute for Health and Care Excellence (NICE) guidance emphasises the importance of behaviour changing weight management services in the treatment of overweight and obesity in young people under the age of 18 years (NICE 2013). However, the guidelines show that there is inconsistent evidence on the long-term effect of such interventions. The short-term effect of behaviour changing interventions on weight loss has been reported in a previous review (Wilfley 2007). Our results add to the evidence base and demonstrate that in trials with longer follow-up at 18 to 24 months, weight loss is maintained. Group-based interventions have been recommended by NICE and our review is consistent in that there were no differences between group-based and individually delivered interventions.

Overall the findings of our review are consistent with previous systematic reviews examining the effect of behaviour changing interventions for the treatment of childhood obesity (Kelly 2008;

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 27 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Ruotsalainen 2015; Whitlock 2010). Several reviews have guestioned the optimal length of behaviour changing interventions (Ho 2012; Kelly 2008; Wilfley 2007), we found that both shortterm interventions (less than six months) and long-term interventions (greater than six months) have a favourable effect on BMI, although in subgroup analyses longer interventions seemed to produce a greater effect on BMI. We found inconsistent evidence on the effect of behaviour changing interventions on dietary intake as reported by one previous systematic review (Collins 2006). One previous review reported the beneficial effect of physical activity on quality of life (Penedo 2005), we found similar favourable effect of behaviour changing interventions on quality of life but not selfesteem. The current review synthesises the most up-to-date and highest-quality research available on the effectiveness of different types of behaviour changing interventions for treating overweight or obesity in adolescents aged 12 to 17 years on a large range of outcomes. Future updates will incorporate the large number of ongoing trials which may strengthen this evidence base.

#### AUTHORS' CONCLUSIONS

#### Implications for practice

We explored the impact of different types of behaviour changing interventions on adolescents being overweight and obese. Overall, there is low-to-moderate quality evidence that behaviour changing interventions reduce measures of body weight including BMI, BMI z score and weight change in adolescents. Additionally, lifestyle interventions seem to reduce indicators of adiposity such as percentage of body fat, waist circumference and total fat mass. There is low quality evidence that behaviour changing interventions have a moderate effect on health-related quality of life. There is inconclusive evidence on the effects of behaviour changing interventions on self-esteem, dietary intake and physical activity in adolescents. Most of the evidence is from multicomponent interventions which include a combination of behavioural, dietary and physical activity interventions. We found no subgroup differences for type of intervention, behavioural approach, mode of delivery or setting. Similar levels of weight reduction are seen in trials with longer follow-up periods of up to two years suggesting that weight loss is maintained in these studies. However, the results of this review should be interpreted with caution as most of the evidence was rated as low quality due to inconsistency, indirectness or risk of bias for many of the outcomes measured. The risk of adverse events could not be assessed reliably as they were not measured by most of the trials.

#### Implications for research

This systematic review identified 50 ongoing trials of behaviour changing interventions targeting adolescent overweight and obesity and incorporation of the results of these when they become available may strengthen the evidence base. Further research is required to determine whether the interventions have any adverse effects. Economic data are needed and trials reporting the costs of behaviour changing interventions should be measured and reported. Consistent measures of health-related quality of life, self-esteem, dietary and physical activity outcomes using validated tools should be used in future research and reports should provide adequate and transparent methodological details such as allocation concealment, blinding, attrition, selective reporting and validity of tools. Higher quality trials are required as the current evidence is of low methodological quality.

#### ACKNOWLEDGEMENTS

We thank Drs Carrel, Christie, DeBar, Ebbeling, Ford, Grey, Ives, Krude, Makkes, Norman, Pbert, Pitetti, Savoye, Wengle and Wiegan, for providing additional information about their trials. We thank Ms Jennifer Cooper for her help with the screening. We thank the Cochrane Editorial Unit (Toby Lasserson) for reviewing this work. We thank the Metabolic and Endocrine Disorders Group editorial team (Bernd Richter) for extracting the German study. We thank Mr Graham Hewitt for translating a Spanish paper to confirm its status as excluded, Dr Karoline Freeman for translating a German publication to confirm its status as excluded, Dr Huayi Huang for translating a Chinese publication to confirm its status as excluded and Dr Soroush Abulfatehi for translating an Iranian publication to confirm its status as excluded. We acknowledge the editorial contributions by Gudrun Paletta and Bernd Richter (Cochrane Metabolic and Endocrine Disorders Group).

# CHARACTERISTICS OF STUDIES

# Characteristics of included studies [ordered by study ID]

# Bean 2014

| Methods              | Parallel RCT, randomisation ratio: 1:1, superiority design  |
|----------------------|---|
| Participants         | <b>Inclusion criteria</b> : aged 11-18 years; BMI $\geq$ 85th percentile for age and gender (CDC 2000); parent willing to participate; an identified primary care physician; no underlying medical condition which would preclude weight loss through behavioural intervention <b>Exclusion criteria</b> : - <b>Diagnostic criteria</b> : as above  |
| Interventions        | <ul> <li>Number of study centres: one</li> <li>Treatment before study: all participants had been enrolled in the TEENS RCT. Parents attended biweekly groups. Participants met on alternating weeks with a dietitian and behavioural support specialist for 6 months. Supervised physical activity at least 3 times per week</li> <li>Description of interventions</li> <li>MI Values : 3 main components of TEENS family-based intervention are physical activity, dietary intervention and behaviour support. MI Values targets adolescents alone to enhance autonomy for change. 2 × 30-minute sessions at weeks 1 and 10. Trained interventionists were independent of TEENS. Participants selected target behaviours and included TEENS participation, diet, exercise or a combination. Session 1 included a values clarification exercise, session 2, explored progress in TEENS, re-examined value/ behaviour congruency and elicited participant ideas for change</li> <li>Education control : 30-minute videos focused on healthy eating and exercise for adolescents at weeks 1 and 10. Participants complete a knowledge quiz to ensure treatment adherence</li> <li>All participants proceeded with TEENS multidisciplinary obesity treatment programme as usual</li> </ul> |
| Outcomes             | Outcomes reported in abstract of publication: adherence (overall, dietitian visits, behavioural support visits)   |
| Study details        | Run-in period: none<br>Study terminated early: no<br>Trial identifier: NCT00167830  |
| Publication details  | Language of publication: English<br>Non-commercial funding<br>Publication status: peer-reviewed journal   |
| Stated aim for study | Quote from publication: "to investigate if brief (two-session) MI can enhance treatment effects among adolescents with obesity enrolled in a multidisciplinary treatment [the T. E.E.N.S. (Teaching Encouragement Exercise Nutrition Support) Program]."  |
| Notes                | Implemented within the TEENS programme. Publication reported no eligible outcomes   |

| Incomplete outcome data (attrition bias)<br>Objective outcomes                     | Unclear risk | Quote from publication: "The analysis was<br>intention-to-treat, where we used data from<br>all adolescents for whom data were available<br>on the basis of the group to which they were<br>allocated, regardless of their adherence to<br>the protocol (attendance)."<br>Comment: reported and reasons explained<br>ITT is a modified ITT as only those who<br>had data were included |
| Selective reporting (reporting bias)   | High risk    | Comment: quality of life, blood lipids, fat-<br>mass and fat-free mass not reported  |
| Other bias   | Unclear risk | Comment: no participants in the control<br>arm attended primary care and received the<br>intervention  |

# Brennan 2013

| Methods      | Cross-over RCT, randomisation ratio: 1:1, superiority design   |
|--------------|--|
| Participants | Inclusion criteria: aged 11-19 years, overweight or obese according to the international cut-off points for BMI in children, living with a parent or adult carer who was prepared to be involved in treatment<br>Exclusion criteria: had an intellectual or physical disability that prevented them from participating in the programme<br>Diagnostic criteria: as above |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 46 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

| Interventions | Number of study centres: 2<br>Treatment before study: none<br>Description of interventions<br>M : individual sessions aimed at improving body composition, cardiovascular fitness, im-<br>prove eating habits, physical activity habits and promote positive psychosocial function-<br>ing by moving participants closer to the Australian recommendations. The programme<br>aimed to instigate small maintainable improvements. Theoretical basis<br>Sessions included a review of the previous session, discussion of homework, goal achieve-<br>ment and monitoring; discussion, questions and practice of strategies; setting of exer-<br>cises for the session and assisted with setting goals; summary of the session material and<br>setting of home practice tasks. Adolescents were then given the choice of attending the<br>remaining sessions alone, or with the support of a parent. 12 sessions over 4-6 months<br>(psycho-education; eating behaviour; physical activity; healthy food choices; exercise;<br>behaviour charts and barriers; recognising thoughts and emotions; helpful thoughts and  |
|---------------|---|
|               | <ul> <li>emotions; assertive communication; problem solving and planning; staying on track; maintenance and closure). Between session 11 and 12 had a telephone call, maintaining change. Weekly sessions for the first 10 weeks</li> <li>Parents and adolescents received a programme workbook. Between sessions, adolescents were encouraged to monitor their behaviour change goals and record their eating and physical activity habits. The physical activity component aimed to promote physical activity habits consistent with guidelines recommending at least 60 minutes of moderate-to-vigorous physical activity per day and no more than 2 hours per day in noneducational screen activities. Rather than specifying goals in terms of specific caloric intake or expenditure targets, aimed to move participants closer to recommendations for eating such as consumption of a variety of foods from each of the 5 food groups (cereals, vegetables, fruit, diary, and meat products and alternatives), the selection of lowfat alternatives, and the consumption of water</li> <li>Parental support: provided with written session materials for sessions 7 (strengthening parent adolescent relationship), 8 (encouraging appropriate behaviour) and 9 (discouraging inappropriate behaviour)</li> <li>Maintenance phase: while the control group given the intervention telephone call sessions were completed every second week and a face-to-face session at 3 months which was followed by monthly telephone call session and a final face-to-face session conducted at 6 months</li> <li>Researcher received training in MI</li> <li>Control : wait list control - offered the intervention after 6 months (postintervention)</li> </ul> |
| Outcomes      | <b>Outcomes reported in abstract of publication</b> : weight control behaviour, impulse regulation, social support from family and parent-adolescent problem communication, treatment acceptability, body composition (body fat, % body fat, lean mass) and anthropometric measures (weight, BMI, BMI-for-age z score and percentiles), cardiovascular fitness  |
| Study details | Run-in period: none<br>Study terminated early: no<br>Trial identifier: ACTRN12610000111077  |

| Methods       | Parallel RCT, randomisation ratio: 1:1, superiority design   |
|---------------|--|
| Participants  | Inclusion criteria: BMI > 95th percentile for age<br>Exclusion criteria: -<br>Diagnostic criteria: as above  |
| Interventions | <ul> <li>Number of study centres: unclear<br/>Treatment before study: none</li> <li>Description of interventions</li> <li>Behaviour changing-focused, fitness-oriented gym classes : class size limited to 14<br/>students to allow for increased instructor attention, increased opportunity for motivation<br/>and less time standing in line. The curriculum was personalised to match the student's<br/>skill levels and encourage student participation. Competitive games were de-emphasised,<br/>and behaviour changing focused activities (walking, cycling and snowshoeing) were<br/>encouraged. A consistent warm-up plan brought students into movement participation<br/>as quickly as possible soon after they entered the gym. Typical movement time was 42<br/>minutes of a 45-minute class period, as children did not change clothes for this class to<br/>increase activity time. Skills were taught with the class broken down into groups of 2 for<br/>promoting more movement and less time watching. The ethos of the class encouraged<br/>physical fitness, less self-conscious focus on appearance and full group participation.<br/>Training for instructors not stated</li> <li>Standard gym classes : movement time averaged 25 minutes of the 45-minute period.<br/>Participated in the traditional physical education classes of 35-40 students. The same class<br/>topics (e.g. football, mile run/walk, kickball) were taught as in the intervention group,<br/>but in a different format, as typical issues in the traditional class were a greater range of<br/>skill levels, longer lines during skill development drills and larger numbers of students<br/>on teams when games were played. These issues tended to result in less movement and<br/>a tendency for students to hold back and not enter into play</li> <li>For both groups: 36-week (9-month) intervention, 90 sessions. The frequency of classes<br/>was 5 times every 2 weeks for a 45-minute class period. All received a small nutrition<br/>education component. This consisted of educational handouts to participants to develop<br/>healthier eating habits. The nutrition portion focuses on the Food G</li></ul> |

|               | management or diseases affecting absorption or processing of nutrients <b>Diagnostic criteria</b> : as above  |
|---------------|---|
| Interventions | <ul> <li>Number of study centres: not clear<br/>Treatment before study: none</li> <li>Description of interventions</li> <li>Stepped-down care : based on a combination of Chronic Care Model and social cognitive<br/>theory. Chronic Care Model provided a conceptual framework for the healthcare delivery<br/>for adolescents with obesity of chronic illness management in a primary care setting.<br/>Chronic Care Model emphasises interdisciplinary team input. Within the Chronic Care<br/>Model framework, social cognitive theory constructs of behaviour self-management were<br/>applied and included: building self-efficacy, goal setting, feedback, identifying barriers<br/>and social support. The intervention followed modified recommendations from the<br/>American Academy of Pediatrics for treatment of childhood obesity and consisted of 3<br/>× 4-month steps. The goal was for adolescents to lose at least 4 lb every 4 months. If the<br/>participant did not meet the goal, then the step was repeated. If a 4-lb weight loss was<br/>achieved, the participant was 'stepped-down' to the next level of reduced intensity. The<br/>number and frequency of treatment elements varied for each intervention step. At the<br/>start, the physician provided brief counselling on healthy behaviours. If progress was not<br/>made, then follow-up occurred and focused on weight management strategies. Face-to-<br/>face health educator visits occurred monthly in step 1 and bi-monthly in step 2 and were<br/>available to the child and parent, but the parent was not required to attend. Biweekly<br/>telephone calls were used to review progress and help adolescents set new goals and<br/>discuss barriers and solutions, and speak to parent to reinforce parental involvement and<br/>emphasise importance of healthy changes in the home environment to encourage goal<br/>attainment. Diet and physical activity education materials were distributed to adolescents<br/>and their parents at each visit. Pedometers were distributed at the initial health educator<br/>visit to monitor physical activity and help participants set appropriate physical activity<br/>goals&lt;</li></ul> |
| Outcomes      | Outcomes reported in abstract of publication: BMI, adiposity, biometric outcomes  |
| Study details | <b>Run-in period</b> : 2-week run-in screening programme was conducted. Adolescent-parent dyads were asked to perform some of the activities that would be required of them if they were to be enrolled in the intervention trial. These tasks included attending a measurement visit; scheduling and completing a telephone call with a study staff member; locating a food item at home, reading the food label and describing the nutrition content; tracking basic food intake and physical activity in a written diary over 4 days; and scheduling and attending a follow-up appointment <b>Study terminated early</b> : no <b>Trial identifier</b> : -  |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 106 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. Resnicow 2005

| Resnicow 2005       |   |
|---------------------|---|
| Methods             | Cluster RCT, randomisation ratio: 1:1, superiority design   |
| Participants        | Inclusion criteria: African-American girls aged 12-16 years and BMI > 90th percentile<br>for age and gender, churches where the majority of members' household income was<br>above USD40,000<br>Exclusion criteria: unclear<br>Diagnostic criteria: used the 90th percentile as inclusion cut-off point rather than<br>the 85th percentile based on formative research and pilot studies. Girls on the lower<br>end of the obesity continuum, i.e. 85th to 90th percentile, were different behaviourally<br>and psychologically, and combining girls from the low and high ends of the obesity<br>continuum would adversely affect group cohesion   |
| Interventions       | Number of study centres: 10<br>Treatment before study: none<br>Description of interventions<br>High intensity (24-26 sessions) : girls attended weekly group behavioural sessions.<br>Parents were encouraged to attend sessions (around 12 sessions). Each group session<br>included an experiential, interactive behavioural activity, at least 30 minutes of mod-<br>erate-to-vigorous physical exercise, and preparation or consumption (or both) of low-<br>fat, portion-controlled meals or snacks. Target behaviours included: increased fruit and<br>vegetable intake, decreased fat intake, decreased fast-food intake, decreased sedentary<br>behaviour and increased physical activity. Girls were taught to reshape their target be-<br>haviours using the principles of substitution, moderation and abstinence. Girls focused<br>their behaviour change on target foods or priority behaviours identified or selected by<br>the girls. At the beginning of each intervention cycle, girls only attended a 1-day retreat<br>where participants completed a low ropes course and team building activities, ate healthy<br>portion-controlled meals and attended a group session on hunger and satiety. All girls<br>received a 2-way paging device. Messages, developed by the girls based on their target<br>foods and activity patterns, were sent to them throughout the day and in key times when<br>they needed reminders about their eating or physical activity. Received 4-6 MI calls by<br>telephone over the 6 months of intervention to support and help in behavioural change<br><b>Moderate intensity (6 sessions) control</b> : sessions were selected from the larger pool of<br>sessions delivered to the high-intensity group. Parents were encouraged to attend sessions<br>(3 sessions). Topics included fat facts, barriers to physical activity, fad diets, neophobia<br>(i.e. fear of new foods) and benefits of physical activity. Girls did not receive the 2-way<br>pagers, MI telephone calls or kick-off retreat |
| Outcomes            | Outcomes reported in abstract of publication: BMI units and % body fat  |
| Study details       | <b>Run-in period</b> : churches were contacted either by telephone or in-person and adminis-<br>tered a brief screening instrument that queried their membership numbers and socioe-<br>conomic status<br><b>Study terminated early</b> : no<br><b>Trial identifier</b> : -   |
| Publication details | <b>Language of publication</b> : English<br><b>Other funding</b> : "given that the sponsoring agency was unable to provide any additional<br>funding, we were able to complete the study in only 10 of the projected 12 churches."<br><b>Publication status</b> : peer-reviewed journal   |

|---------------|--|--|
|               | Treatment before study: none   |  |
|               | Description of interventions   |  |
|               | <b>Healthy Habits</b> : computer and telephone intervention. Adolescents engaged in a computer program after baseline assessment, the program was adapted from PACE+ software designed for adolescents and modified for overweight adolescents. It assessed eating, physical activity and sedentary behaviour and guided adolescents through individualised plans generated to increase physical activity or decrease sedentary behaviour and decrease dietary fat or increase fruits/vegetables or decrease overeating/snacking. Plan generation included identifying benefits, barriers and specific strategies to achieve goals. Action plan summaries were generated, and a provider summary was produced for the behaviours targeted by the adolescent. Met with a paediatrician to discuss action plans (tailored physician counselling), and approximately 1 week after the clinic visit met the study author to discuss upcoming mail and telephone contacts and to learn food selfmonitoring. Calls from a telephone counsellor 1 week later detailed telephone scripts to address adolescents' weight change since the last call, the link between weight change and eating and physical activity behaviours, instruction and feedback on self-monitoring, goals and behavioural skills Provided with a manual and information sheets. Self-monitoring of food and beverage intake and calories consumed Foods were categorised into green, red or no colour foods. Green defined as $\leq 1$ g of fat per serving, 150 calories per serving and providing a good source of $\geq 1$ valuable dietary components (e.g. calcium, fibre or protein), red foods were defined as having $\geq 5$ g of fat per serving or were diet versions of high-fat foods. The eventual green food goal was 40 green food servings (based on standard serving sizes) or more per week, and the red food goal was 15 red food servings per week |  |
|               | minutes of at least moderate-intensity physical activity on 5 days per week with gradual increases from baseline<br>Overall duration 16 weeks with 13 sessions.<br>Paediatricians trained with the study protocol and telephone counsellors (with at least a Bachelor's degree in psychology or nutrition) received weekly supervision<br><b>Standard care control</b> : non-tailored physician-counselling session. 1 session in the 16-week treatment period by the same paediatrician as the intervention group. Assessed/<br>encouraged the adolescent's motivation for weight-related behaviour change, provided information about short- and long-term health consequences of high weight status and benefits of better weight control, made recommendations for healthful eating consistent with the Food Guide Pyramid, reviewed physical activity recommendations for adolescents (60 minutes per day of at least moderate-intensity physical activity), and encouraged consistency and persistence with health behaviour changes. Used a worksheet to facilitate the discussions. Adolescents encouraged to implement recommended behaviour changes on their own and with the help of their family<br>Adolescents received USD25 for post-treatment and USD25 for follow-up assessment. In the intervention group, a lottery occurred after all adolescents had completed post-treatment assessment for USD50. Adolescents were awarded 1 point each for meeting self-monitoring, physical activity, calorie, green food goals and red food goals each week  |  |

|                      | Oops I Slipped - Understanding a Relapse. Attended the programme twice per week for 6 months and then every other week for an additional 6 months Techniques included self-awareness, goal setting, stimulus control, CST, cognitive behaviour strategies and contingency management. Behaviour modification classes for carers included topics that reflected the challenges that parents verbalised. Classes emphasised the importance of the parents' roles in modelling healthy behaviour change. Motivational tools were used to encourage regular attendance Each class of high-intensity exercise to sustain 65-80% of the age-adjusted maximal heart rate held twice (50 minutes each) and nutrition/behaviour modification once (40 minutes each) per week. Participants were also encouraged to exercise 3 additional days at home per week and to decrease sedentary behaviours. The minimum activity that each participant completed was 100 minutes per week (2 × 50-minute sessions) for the first 6 months and 100 minutes twice per month for the last 6 months The nutrition education component of the weight management programme used a nondiet approach that emphasised low-fat, nutrient-dense foods of moderate portion sizes No details of trainer provided, registered dictitians supervised nutritional component <b>Control</b> : received diet and exercise counselling by registered dictitans and physicians along with brief psychosocial counselling by a social worker. The participant and carer were both involved in setting the nutrition and activity goals to ensure that he clinic plan was realistic and accepted by both. Exercise counselling included decreasing sedentary activities (computer and video games) and finding an activity the participant enjoyed enough to engage in on a regular basis. Nutrition counselling included decreasing intake of juice, switching to diet beverages, switching from whole-fat to low-fat milk and bringing lunch to school vs choosing hot lunch. 30-minute session every 6 months |                       |
|----------------------|--|-----------------------|

|---------------|--|
| Interventions | <ul> <li>Number of study centres: 1.</li> <li>Treatment before study: none.</li> <li>Description of interventions</li> <li>Family-based intervention : an individual consultation with the child psychologist, group intervention with 8-10 participants in each group. Received a treatment manual with the objectives and goals of the treatment and, per session, information about the topics discussed. The focus was on the effort to change habits more than weight reduction goals. Adolescents were made aware of their own actions and their way of living that has led to their obesity</li> <li>Several cognitive behavioural techniques were learned (knowledge, skills and attitude) during the intensive phase of the treatment during 6 bi-weekly sessions of 2.5 hours per session. Each session contained: determination of body weight, homework discussion and evaluation, education, physical activity, role playing, discussing homework for next meeting and set goals linked to educational topics of the session. The educational topics included group bond to encourage peer support, individual motivation for participating, nutritional information and the balance between energy intake and energy expenditure, healthy nutrition, self-control techniques, coping with teasing and being teased, self-image, cognitive strategies and relapse techniques</li> <li>Current physical activity level and sedentary behaviour of the child also reviewed, energy intake versus energy expenditure was evaluated and visualised for the adolescent by a computer program. Options to change or optimise physical and sedentary activities were debated and the participants were advised how to find suitable exercise programmes</li> <li>Taught how to read product labels and obtain information on misleading advertisement and discuss how to deal with meals (breakfast, lunch, diner, 2 healthy snacks), and how to make healthy choices and develop healthy autrition, product information, quantites, eating moments, eating locations, how to help their children and parenting styles F</li></ul> |

| Official title          | Anti-obesity effect of comprehensive diet and sports in girl students with simple obesity or overweight   |
| Stated purpose of study | To investigate the effective antiobesity therapy with comprehensive diet prescription and sports for girl students with simple obesity and overweight |
| Notes                   | Article in Chinese, lack of resources to translate. Contacted author (11 August 2015) for an English version  |

#### Makkes 2015

| Methods       | HELIOS study<br>Type of study: efficacy<br>Allocation: randomised<br>Intervention model: parallel assignment<br>Masking: none<br>Primary purpose: treatment   |
|---------------|---|
| Participants  | <b>Condition</b> : obesity<br><b>Enrollment</b> : 80<br><b>Inclusion criteria</b> : children and adolescents aged 8-18 years referred to Heideheuvel by their own paedia-<br>trician. They must have BMI-SDS $\geq 2.3$ according to the growth curves based on the 4th Dutch National<br>Growth Study of 1997 (this corresponds to the 99th percentile) and comorbidity related to obesity (e.g.<br>obstructive sleep apnoea syndrome, raised insulin, diabetes type 2, liver function disorders, dyslipidaemia,<br>worn out joints) or a BMI-SDS $\geq 3.0$ (this corresponds to the 99.9th percentile)<br><b>Exclusion criteria</b> : having syndromal or chromosomal determined obesity, obesity caused by endocrine<br>disorders (hypothyroidism, Cushing's syndrome, primary hyperinsulinaemia, pseudohypoparathyroidism,<br>acquired (structural) hypothalamic damage) or medicine use (e.g. oral steroids, antiepileptic drugs, antide-<br>pressants), severe psychiatric problems, an IQ < 75 or similar school level or if their parents are not willing<br>to participate in the treatment |
| Interventions | <ul> <li>Intervention A: intensive combined behaviour changing inpatient treatment for 6 months during week-days, followed by biweekly hospital admissions of 2 days for 4 months</li> <li>Intervention B: intensive combined behaviour changing inpatient treatment for 2 months during week-days, followed by biweekly return visits of 2 days during the next 4 months, then followed by 6 monthly return visits of 2 days</li> <li>Comparator: usual care: will receive usual care for 1 year, after which the participants will be randomly allocated to the groups A and B</li> </ul>   |
| Outcomes      | Primary outcome: BMI-SDS (costs of treatment per change in relative BMI)<br>Secondary outcomes: psychological and psychosocial data on issues such as motivation, competence, self-<br>esteem, anxiety and mental stress; cardiovascular risk factors (blood pressure, serum lipids, liver function<br>tests, glucose and insulin); waist circumference; dietary behaviour; eating behaviour, physical activity<br>(sedentary behaviour); quality of life (generic, weigh-specific and health-related quality of life)<br>Other outcome: -  |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 143 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

## Makkes 2015 (Continued)

| Study identifier        | NTR1678.  |
|-------------------------|---|
| Official title          | Health effects of behaviour changing interventions in obese children and adolescents study (Helios) - a randomised controlled trial   |
| Stated purpose of study | Quote: "to compare the cost-effectiveness of these two intensive one-year inpatient treatments to each other and to usual care for severely obese children and adolescents."  |
| Notes                   | Study only intended to compare the 2 active interventions. The thesis states that for 'logistical reasons' they randomised to a wait list control group, review authors assumed as they were only able to take a small number of participants through the interventions at any 1 time. They also randomise to the groups in 2 batches so that every 6 months for 2 years they start a new intervention 1 and 2 with 10 participants each. The flow chart and number of participants do not show the wait list control group but include them when they are included in intervention A and B. There is 1 analysis for the 3 groups (6 and 12 months only as appropriate) which was described as an "additional analysis." For the purpose of the review, the comparison with the wait list control would be relevant; however, there are no numbers included in the analysis, no baseline characteristics and the only data for BMI-SDS is from a figure. Awaiting further clarification from author or publication of the data to know if this group will be analysable |
| NCT00462267             |   |
| Methods                 | Type of study: interventional<br>Allocation: randomised<br>Intervention model: parallel assignment<br>Masking: single blind (outcomes assessor)<br>Primary purpose: treatment   |
| Participants            | Condition: obesity/overweightEnrollment: 215Inclusion criteria: aged 13-15 years, $BMI \ge 90\%$ , 1 or both parent(s) willing to participate in studyassessments and parent sessionsExclusion criteria: $BMI \ge 99\%$ , significant cognitive impairment, pregnant, congenital heart disease thatlimits activity, serious asthma requiring oral prednisone, taking medications that increase appetite   |
| Interventions           | <b>Intervention</b> : enriched behaviour changing intervention, multicomponent group teen and parent sessions, individual telephone-based coaching contact and a distinct collaborative care component with follow-up visits to the youth's primary care provider <b>Comparator</b> : usual care  |
| Outcomes                | <b>Primary outcome:</b> BMI z score<br><b>Secondary outcomes:</b> quality of life, self-esteem, depression, unhealthy eating practices, weight and shape  |
|                         | concerns, sociocultural attitudes toward appearance, satisfaction, dietary intake, personal and family eating patterns, physical activity, sedentary behaviours, personal and family physical activity patterns <b>Other outcome</b> : -  |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 147 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

## ACTRN12611000139976 (Continued)

| Participants            | <ul> <li>Condition: overweight and obesity (≥ 85th centile)</li> <li>Enrollment: 570</li> <li>Inclusion criteria: aged 12-17 years; overweight or obese (≥ 85th centile) according to the age- and gender-specific BMI data from the International Obesity Task Force; Internet access at home or at a location where regular use is possible (i.e. school, library). Recruitment will be restricted to those living in the Melbourne metropolitan area (to facilitate complete follow-up assessments by maximising opportunities to collect height and weight data, and to contain study costs)</li> <li>Exclusion criteria: young people with a known endocrine or chromosomal cause for their obesity; taking prescription medication resulting in weight changes (e.g. prednisolone); complications of overweight that contraindicate moderate physical activity (e.g. orthopaedic disorders); past or current medical diagnosis of a clinical eating disorder (i.e. anorexia or bulimia nervosa, binge eating disorder) or significant health disability or condition which prevents participation</li> </ul>  |
|-------------------------|---|
| Interventions           | <b>Intervention</b> : Internet-based programme for 12 weeks, 1 session per week for self-directed 30-60 minutes. Goals will be set by the participant from a framework recommended within the programme (e.g. to increase moderate activity from 0 to 30 minutes on most days) and reviewed every week, activities will be specific to intervention group but not to each individual. Participants will receive a pedometer and a walking programme to help achieve goal of 60 minutes of moderate-to-vigorous activity per day. Cognitive behaviour aspect of the programme will address self-monitoring, goal setting, stimulus control, social eating, etc Participants will receive feedback at least weekly. Parents of participants will be sent monthly newsletters for the 3 months of the intervention programme with tips on creating a supportive environment. After the 12-week programme is finished, participants will receive monthly follow-up via text or e-mail asking them to review their eating and physical activity habits, and provide feedback. They can also review the materials from the programme <b>Comparator</b> : publicly available generic health information about healthy eating and physical activity at start of 12 weeks treatment period. Information will be presented in both paper and online format (e. g. participant will receive a pack with flyers about the physical activity requirements, healthy eating and planning healthy meals and a sheet with links to websites about the age appropriate healthy eating, physical activity and mental health). No cognitive behaviour element |
| Outcomes                | <b>Primary outcome</b> : reduction in BMI z score<br><b>Secondary outcomes</b> : waist circumference, % body fat, blood pressure, psychological distress, quality of<br>life, eating disorder, programme content satisfaction questionnaire<br><b>Other outcome</b> : adherence   |

Notes

Recruitment status: active, not recruiting. Contacted author (17 January 2017) for trial status

| Trial name or title | Acronym: -  |
|---------------------|---|
| Methods             | <b>Type of study</b> : efficacy study<br><b>Allocation</b> : randomised block design will be used. Obese participants will be randomised to 1 of 3 groups<br>and will be stratified according to age and gender<br><b>Intervention model</b> : single blind (outcome assessors)<br><b>Primary purpose</b> : effect on myocardial function   |
| Participants        | Condition: obesity<br>Enrollment: 100<br>Inclusion criteria: BMI > 95th percentile (age and gender specific), children and adolescents aged 7-16<br>years<br>Exclusion criteria: hypertension (defined as blood pressure > 95th centile for systolic or diastolic values),<br>any history or evidence of heart disease or an abnormal resting or stress echocardiography which indicates<br>it would be unsafe to participate (or both), any chronic disease (e.g. chronic asthma, kidney disease,<br>diabetes, current smoking habits or an orthopaedic/neurological disorder that may limit ability to exercise)<br>, diagnosed attention deficit hypersensitivity disorder and use of steroid medications  |
| Interventions       | <ul> <li>Intervention 1: high-intensity interval training. Walk, run or cycle at 85-95% of their maximal heart rate at intervals of 4 × 4 minutes, with 3-minute active breaks (~ 60% of maximal heart rate) between intervals. Total exercise time 40 minutes</li> <li>Intervention 2: moderate-intensity exercise. Walk, run or cycle continuously at 70% maximal heart rate for approximately 44 minutes to equalise the energy expenditure performed by high-intensity interval training group. Total exercise time 50 minutes</li> <li>Common across interventions: dietary education sessions that will parallel sessions provided to those assigned to the control group. 30-minute session every second week for 3 months, followed by 1 session every 2 months for the next 9 months. Exercise training 3 times per week for 12 months. Months 1-3, 2 supervised sessions in the gym and 1 session at home. Months 4-12, all training at home. Consists of walking or running on a treadmill, or on a bike for the older children</li> <li>Comparator: control: dietary education sessions, 8-10 × 20-minute individual diet intervention sessions over 12 months. A session every second week for 3 months, followed by 1 session every 2 months for the active session sessions, 8-10 × 20-minute individual diet intervention sessions over 12 months.</li> </ul> |
| Outcomes            | Primary outcome: myocardial function (peak systolic tissue velocity)<br>Secondary outcomes: vascular function (flow-mediated dilation assessment), quantity of visceral and sub-<br>cutaneous adipose tissue, myocardial structure and function, body composition, cardiorespiratory fitness,<br>autonomic function, blood biochemistry, physical activity and nutrition<br>Other outcome: -  |

| Official title      | A pilot study to determine the efficacy of a low carbohydrate diet in treatment of adolescents with metabolic syndrome   |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 165 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

## NCT00940966 (Continued)

| Stated purpose of study | Quote: "to determine the effectiveness of two different non-energy restricted controlled carbohydrate programs with the American Diabetes Associations' diet on glycosylated hemoglobin and other diabetes risk factors in obese adolescents with metabolic syndrome, a constellation of symptoms associated with the development of type 2 diabetes and cardiovascular disease." |
|-------------------------|---|
| Notes                   | Trial status completed (according to trial record, accessed 17 August 2016). Contacted author (5 August 2015) for study completion date. Recontacted (6 October 2016) for results/publication   |

## NCT00998413

| Trial name or title | Acronym: Mikado (Multifactorial intervention for children with asthma and overweight)  |
|---------------------|--|
| Methods             | Type of study:interventional<br>Allocation: randomised<br>Intervention model: parallel<br>Masking: open label<br>Primary purpose: prevention   |
| Participants        | <b>Condition</b> : asthma, overweight, obesity<br><b>Enrollment</b> : actual 104<br><b>Inclusion criteria</b> : asthma and overweight (BMI-SDS > 1), aged 6-16 years, living in Southern Limburg<br><b>Exclusion criteria</b> : congenital malformations of the airways or other chronic lung diseases like cystic<br>fibrosis, mental retardation or syndromes, heart disease   |
| Interventions       | <b>Intervention</b> : multifaceted family-based, physical exercise, nutrition, cognitive behavioural therapy, parental sessions and individualised counselling for 18 months. Small groups of 8-12 children. Based on health counselling model. Group exercises (twice per week during initial phase, 3 times per month during the follow-up phase), with a duration of 60 minutes per session guided by an experienced paediatric physiotherapist or a paediatric sport instructor. A dietitian and psychologist guide 18 behaviour changing sessions with a duration of 75-90 minutes. Use a workbook with additional information for each behaviour changing session, homework and space for individualised goal setting. Small presents as incentives for participation and achievements. 3 basic dietary guidelines: healthy food choice, regular eating pattern, and normalised portion sizes. Children receive individualised counselling sessions. Parents follow 10 parental sessions of 60 minutes guided by the dietitian and psychologist General Practitioners and the Paediatric Pulmonology section of the Dutch Society of Paediatrics |
| Outcomes            | <b>Primary outcomes</b> : forced expiratory volume in 1 second (FEV <sub>1</sub> %) predicted value, BMI-SDS<br><b>Secondary outcomes</b> : lung function parameters, inflammatory parameters, asthma control, medication<br>use, asthma symptoms, health-related quality of life, asthma-related quality of life, sleep-related breathing<br>disorders, gastro-oesophageal reflux disease, psychosocial problems, eating behaviour, weight, height, BMI)<br>, waist and hip circumference, 4-fold skinfold measurement, food record, accelerometer output<br><b>Other outcome</b> : -   |
| Starting date       | Study start date: January 2010<br>Study completion date: September 2013  |
| Contact information | Responsible party/principal investigator: Maastricht University Medical Center/Edward Dompeling  |

## NCT00998413 (Continued)

| Study identifier        | NCT00998413.  |
|-------------------------|---|
| Official title          | Secondary prevention of asthma in overweight/obese children by a combined dietary-behavioural-physical activity intervention  |
| Stated purpose of study | Quote: "to determine the efficacy of a multifactorial intervention with weight reduction, behavioural therapy, and physical exercise on the severity and control of asthma in obese children."            |
| Notes                   | Trial status completed (according to trial record, accessed 17 August 2016). Contacted author (22 October 2015) for study completion date but e-mail error. Recontacted (6 October 2016) and e-mail error |

## NCT01023139

| Trial name or title | Acronym: AOS  |
|---------------------|---|
| Methods             | Type of study: interventional<br>Allocation: randomised<br>Intervention model: parallel assignment<br>Masking: open label<br>Primary purpose: treatment   |
| Participants        | <ul> <li>Condition: overweight</li> <li>Enrollment: estimated 100</li> <li>Inclusion criteria: BMI ≥ U. weighted mean of the 95th percentile based on age and gender; willing to lose weight to meet and continue study medication for the 12-month treatment period and meet personal weight loss goal; willing to not start any new weight loss products; males or non-pregnant females (pregnancy determined by self-report); females of childbearing potential if practicing acceptable method of contraception</li> <li>Exclusion criteria: weight loss ≥ 10 lb in previous 3 months; active gastrointestinal disorders (except gastro-oesophageal reflux disease); at least 2 out of 3 blood pressure readings either systolic or diastolic ≥ 95 percentile for height and age or pulse ≥ 95 beats per minute at initial visit; drug-treated diabetes mellitus or hypertension; drugs or supplements (or both) administered for the first time or withdrawn during the past 6 months which have a significant impact on body weight or digestion; inability or unwillingness to comply with protocol requirements; unwilling to avoid consumption of alcoholic beverages; smoking or has started a smoking cessation programme within the past 6 months; previous treatment with prescription sibutramine; history of recurrent nephrolithiasis; major psychiatric or eating disorders; kidney, liver or thyroid disorder; drugs that are contraindicated; cardiovascular disease; history of bleeding problems, migraine headaches or seizures; stroke; history of pulmonary hypertension, osteopenia or osteoporosis; current recreational drug use or overused prescription medications; history of glaucoma; pregnancy</li> </ul> |
| Interventions       | <b>Intervention</b> : continuing behavioural therapy. Study uses a multidisciplinary approach along with phar-<br>macotherapy (use of Meridia) to motivate and establish behaviour changes in adolescents (aged 12-18<br>years) during the first phase of the study. The group will continue on monthly behaviour modifications and<br>be evaluated at 3 and 6 months. This arm follows the end of the phase 1 which incorporates behavioural<br>therapy, nutrition counselling and pharmacotherapy with sibutramine while medically supervised. Partic-<br>ipants randomised to this arm no longer receive medication and will receive behavioural therapy once per<br>month and then evaluated at 3 and 6 months for weight loss maintenance<br><b>Comparator</b> : no intervention: standard of care. No intervention following phase 1 of the study done  |

| Official title          | Efficacy in adolescents of continued behavior modification following a six month sibutramine-based weight management intervention   |
| Stated purpose of study | Quote: "This study uses a multidisciplinary approach along with pharmacotherapy (use of Meridia) to motivate and establish behavior changes in adolescents (12-18yo) during the first phase of the study."                                |
| Notes                   | Trial record stated, "The recruitment status of this study is unknown because the information has not been verified recently."  |

#### NCT01221220

| Trial name or title | Acronym: -   |
|---------------------|--|
| Methods             | Type of study: efficacy<br>Allocation: randomised<br>Intervention model: parallel<br>Masking: single blind (outcome assessor)<br>Primary purpose: treatment  |
| Participants        | Condition: obesity<br>Enrollment: 160<br>Inclusion criteria: aged 8-15 years, obese (BMI > 95th percentile on the 2000 CDC BMI reference) on<br>the date of randomisation. Standard Stanford Pediatric Weight Control Program eligibility criteria apply:<br>both child and parent/guardian must want to join, both child and at least 1 parent/guardian must agree to<br>attend sessions and must agree to not miss > 2 consecutive sessions<br>Exclusion criteria: diagnosed with a medical condition affecting growth (a genetic or metabolic disease/<br>syndrome associated obesity, type 1 diabetes, type 2 diabetes taking medication, chronic gastrointestinal<br>diseases, chronic renal diseases, uncorrected structural heart disease, heart failure, heart transplant, anorexia<br>nervosa or bulimia nervosa or binge eating disorder (present or past), AIDS or HIV infection, pregnancy)<br>; taking medications affecting growth (systemic corticosteroids > 2 weeks in the past year, insulin, oral<br>hypoglycaemic drugs, thyroid hormone, growth hormone); have a condition limiting their participation<br>in the interventions (e.g. unable to participate in routine physical education classes at school, requiring<br>oxygen supplementation for exertion, developmental or physical disability preventing participation in |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 168 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

## NCT01221220 (Continued)

|                         | interventions, children or parents/guardians who cannot medically participate in mild dietary restrictions, increased physical activity for any reason, or a combination of these); have a condition limiting participation in the assessments (child or primary carer unable to read surveys in English or Spanish, child $\geq 2$ grade levels delayed in school for reading and writing in his/her native language); unable to read, understand or complete informed consent in English or Spanish; plan to move from the San Francisco Bay Area within the next 18 months |
|-------------------------|---|
| Interventions           | <b>Intervention</b> : behavioural treatment + environmental strategies. 6-month, family-based, group, be-<br>havioural weight control programme + home-based environmental intervention<br><b>Comparator</b> : active comparator: behavioural treatment only. 6-month, family-based, group, behavioural<br>weight control programme   |
| Outcomes                | Primary outcome: BMI<br>Secondary outcomes: waist circumference, triceps skinfold, resting heart rate, dietary intake/meals eaten<br>with television, weight concerns, depressive symptoms, daily energy intake, physical activity, systolic and<br>diastolic blood pressure, fasting blood lipids, insulin/glucose metabolism<br>Other outcome: -  |
| Starting date           | Study start date: September 2010<br>Study completion date: February 2015 (estimated)  |
| Contact information     | Responsible party/principal investigator: Thomas Robinson Stanford University   |
| Study identifier        | NCT01221220.  |
| Official title          | Environmental strategies & behavior change to reduce overeating in obese children   |
| Stated purpose of study | Quote: "There is a need for effective weight control methods for obese children. Environmental strategies such as reducing the size of dishware and serving utensils, storing food out of view and reducing food consumption while watching television may reduce food intake without requiring conscious, cognitive self-control. The investigators propose to test these methods when added to a current state-of-the-art behavioral program."  |

| Stated purpose of study | Quote: "This study will test whether treatment can be delivered via an Android app and whether such treatment reduces obesity."  |
| Notes                   | Some conflicting information between the protocol and clinical trials record, e.g. sample size and outcomes.<br>Trial record stated, "The recruitment status of this study is unknown because the information has not been<br>verified recently" (accessed 18 August 2016) |

## NCT01840631

| Trial name or title | Acronym: -  |
|---------------------|---|
| Methods             | Type of study: intervention<br>Allocation: randomised<br>Intervention model: parallel<br>Masking: open label<br>Primary purpose: treatment  |
| Participants        | <ul> <li>Condition: obesity</li> <li>Enrollment: 80</li> <li>Inclusion criteria: aged 9-17 years, BMI percentile for age of ≥ 95, able to attend monthly sessions with a parent or guardian (or both)</li> <li>Exclusion criteria: diabetes at baseline, mental or psychological disease that would interfere with understanding, disease or medication causing obesity or weight loss, and participants in an alternative weight management programme, impaired glucose tolerance</li> </ul>   |
| Interventions       | <b>Intervention</b> : group nutritional counselling for a total of 6 classes. Classes meet 1 time per month for 60 minutes (30 minutes for dietetic session and 30 minutes for discussion/questions). Classes cover topics including nutrition, exercise and behaviour to promote healthy eating. All content developed prior to starting the intervention. Each group session have a maximum of 7 children with 1 parent/carer per child and a minimum of 5 children with a carer. All groups receive standard of care for physical fitness counselling which includes recommending 1 hour of physical activity per day and limiting screen time to < 2 hours per day. All groups evaluated for depression and appropriately referred if found to be depressed. Behavioural strategies, such as mindful eating, included in the nutrition education (participants receive the same information in both interventions) <b>Comparator</b> : individual nutritional counselling (usual care): nutritionist conducts the nutritional counselling with 1 family at a time. Individual sessions once per month for 30 minutes for a total of 6 sessions. |

- denotes not reported

<sup>a</sup>According to power calculation in study publication or report.

<sup>b</sup>Duration of follow-up/(duration of intervention).

 $^{c}$  For number of participants finishing the study the publication stated that 26 participants in the normocaloric diet + physical activity group and 25 participants in the no intervention groups finished the study but also reported that there were four dropouts/withdrawals in the normocaloric diet + physical activity group and eight dropouts/withdrawals in the no intervention group.

<sup>*d*</sup>At 6 months, only 115 (46%) children in the multicomponent intervention group and 135 (54%) children in the standard care group participated in a follow-up examination.

<sup>e</sup>Numbers did not add up accurately because of missing data per intervention/comparator groups in some trials.

C: comparator; CBT: cognitive behavioural therapy; FBT-PO: family-based therapy for paediatric overweight; GI: glycaemic index; GL: glycaemic load; I; intervention; ITT: intention to treat; n: number of participants; N/A: not applicable; RCT: randomised controlled trial; SMS: short message service.

| Study        | Tool   | Outcome                          | Findings  |
|--------------|--|----------------------------------|---|
| Norman 2016  | Child's BMI - median BMI for age<br>and gender)/median BMI for age<br>and gender × 100 | % over median BMI                | At 12 months, a significant treat-<br>ment effect was observed in boys in<br>the stepped care group compared to<br>the enhanced usual care group (P =<br>0.002)                                 |
| Schranz 2014 | Scales   | Body mass (kg), mean ± SD        | At 12 months, there was no signif-<br>icant difference (P= 0.69) between<br>the intervention (99.3 $\pm$ 16.6; 30<br>participants) and control group (104<br>$\pm$ 27.1; 26 participants)       |
|              | Calliper   | Sum of skinfolds (mm), mean ± SD | At 12 months, there was no sig-<br>nificant difference (P= 0.86) be-<br>tween the intervention (249.4 $\pm$ 72.<br>9; 30 participants) and control group<br>(248.1 $\pm$ 96.9; 26 participants) |

#### Table 2. Anthropometric data

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 273 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

| Carraway 2014 | By comparing actual BMI to BMI at the 50th percentile | % overweight)                                   | Participants in both groups were able<br>to reduce % overweight from base-<br>line to post-test by 1.98% and from<br>baseline to follow-up by 1.48%   |
|---------------|---|---|---|
|               | DXA   | % fat   | Reduction from baseline to postin-<br>tervention tended towards signifi-<br>cance. However, this reduction was<br>reversed across follow-up   |
| Pakpour 2015  | Bioelectrical impedance analysis                      | % fat, mean ± SD                                | At 12 months, the motivational<br>interview + parental involvement<br>group had significantly (P = 0.001)<br>lower body fat ( $42.32 \pm 3.56\%$ ; 118<br>participants) compared to the con-<br>trol ( $45.33 \pm 4.86\%$ ; 115 partici-<br>pants) but was not superior (P= 0.<br>38) to the motivational interviewing<br>group ( $45.62 \pm 4.32\%$ ; 113 partici-<br>pants) |
| Kong 2014     | Bioimpedence  | % visceral fat, median (interquartile<br>range) | At 6 months, no significant reduc-<br>tion of visceral fat in either the low<br>GI group (from 14.2 (10.8 to 19.8)<br>to 12.0 (10.0 to 19.0); 27 partici-<br>pants) or the control group (from 12.<br>5 (9.0 to 19.0) to 13.5 (7.5 to 20.5)<br>; 34 participants)   |
| Brennan 2013  | Body scan   | Trunk lean mass (kg), mean ± SD                 | At 6 months, the intervention group<br>had lower truncal lean mass (21.67<br>$\pm$ 4.72; 42 participants) compared to<br>the control group (21.99 $\pm$ 3.96; 20<br>participants)   |
| Toulabi 2012  | Anthropometric tape                                   | Hip circumference (cm), mean ± SD               | At 6 months, the intervention group<br>had a significantly lower (P = 0.001)<br>circumference (105.18 $\pm$ 7.38; 76<br>participants) compared to the con-<br>trol (109.80 $\pm$ 6; 76 participants)  |
| Vos 2011      | Anthropometric tape                                   | Waist circumference-SDS, MD,<br>95% CI          | At 12 months, the mean change in<br>the intervention group (-0.6, -1.2 to<br>-0.00; 32 participants) was signifi-<br>cantly lower (P = 0.03) compared to<br>the control group (-0.2, -0.7 to 0.5;<br>34 participants)   |

## Table 4. Behavioural change - dietary intake

| Study         | Tool                   | Outcome                                  | Findings  |
|---------------|------------------------|--|---|
| Pbert 2013    | 24-hour dietary recall | Fat (% of energy), MD, 95% CI            | At 6 months, no significant change<br>in the intervention arm (1.21, -1.<br>99 to 4.41;2 participants) and the<br>control arm (MD 1.19, 95% CI<br>-1.92 to 4.30; 40 participants) for<br>fat intake   |
| Ebbeling 2003 | 7-day food record      | Fat (% of energy), mean ± SD             | At 12 months, a significant decrease (P= 0.03) in the conven-<br>tional reduced fat arm (from $33 \pm 1$ to 29 $\pm 3$ ; 7 participants) but<br>tended to increase in the glycaemic<br>load arm (27 $\pm 2$ to 29 $\pm 3$ ; 7 par-<br>ticipants)      |
| Saelens 2002  | 2-day dietary recall   | Fat (% of energy), mean ± SD             | At 7 months, no significant change<br>in the Healthy Habits intervention<br>arm (from $33.9 \pm 8.8$ to $32.9 \pm 9$ .<br>4; 18 participants) and the typical<br>care arm (from $34.3 \pm 4.9$ to $35.6 \pm 6.4$ ; 18 participants)                   |
| Kong 2014     | 3-day dietary record   | Protein (% of energy), mean ± SD         | At 6 months, the low GI group had<br>a significantly (P = $0.002$ ) higher<br>protein intake (17.9 ± 3.8; 34 par-<br>ticipants) compared to the control<br>(15.9 ± 2.7; 27 participants)  |
| Ebbeling 2003 | 7-day food record      | Protein (% of energy), mean ± SD         | At 12 months, there was no signif-<br>icant change in protein intake in<br>the glycaemic load arm (from 17<br>$\pm$ 2 to 20 $\pm$ 1; 7 participants) or<br>the conventional reduced fat group<br>(from 16 $\pm$ 1 to 18 $\pm$ 2; 7 partici-<br>pants) |
| Kong 2014     | 3-day diet record      | Carbohydrate (% of energy), mean<br>± SD | At 6 months, there was no signif-<br>icant difference for carbohydrate<br>mean intake between the low GI<br>group (50.8 $\pm$ 8.1; 34 participants)<br>and the control group (49.5 $\pm$ 6.6;<br>27 participants)                                     |
| Ebbeling 2003 | 7-day food record      | Carbohydrate (% of energy), mean<br>± SD | At 12 months, there was a non-sig-<br>nificant decrease (P = $0.07$ ) in the<br>reduced glycaemic load arm (from  |

| Jelalian 2016      | CBT for depression and healthy lifestyle plus ex-<br>ercise: CBT treatment adapted into 1 integrated<br>protocol that addresses depression, an exercise<br>component, weight and advice regarding healthy<br>eating. Weekly 60-minute group aerobic exercise<br>sessions were required and facilitated by a phys-<br>iotherapist                                      | CBT for depression treatment only  |
|--------------------|---|--|
| Norman 2016        |   | Enhanced usual care. 1 counselling visit, 1 health<br>education visit, materials and monthly mailings<br>of weight-related materials |
| Hofsteenge 2014    | Group education on dietary behaviour, physical activity and energy balance  | Referral to a dietitian  |
| Schranz 2014       | Resistance training   | No intervention  |
| Visuthranukul 2015 | Low GI diet. Monthly visits for 6 months. Each<br>visit consisted of a 2-hour, small class teaching<br>session with parental participation (4-5 families<br>per class)  | Conventional diet. Monthly visits for 6 months<br>(1 per month for 6 months)   |
| Wong 2015          | Monthly dietary counselling with a registered di-<br>etitian and daily text messaging   | Monthly dietary counselling with a registered di-<br>etitian and daily text messaging  |
| Pakpour 2015       | I1: MI. Physical activity and dietary intervention,<br>40-minute session weekly for 6 weeks   | Passive control: no details  |
|                    | I2: MI + parental involvement. As for MI group with 1-hour parental session after 6 weeks   |  |
| Bean 2014          | I1: MI values. 2 sessions, values clarification, re-<br>examined value/behaviour congruency and ideas<br>for change + TEENS family-based intervention   | Education control. Watched 2 educational videos, week 1 and week 10 + TEENS family-based intervention                                |
| Carraway 2014      | 12-week mentor-led exercise programme. Each<br>adolescent paired with a college student mentor<br>who was majoring in exercise physiology or re-<br>lated field. Mentor/mentee pairs met for 3 exer-<br>cise sessions per week, each lasting 1 hour. Activ-<br>ity type varied by session and was decided collab-<br>oratively and included exercise machines (tread- | Wait list control  |

|                   | mill, stationary bike, elliptical), racquetball, ten-<br>nis, group outdoor activities (flag football, tag)<br>. Mentees wore heart rate monitors to monitor<br>exercise intensity. In addition to exercise, the 12-<br>week programme included individual weekly cog-<br>nitive behavioural-based challenges, or lessons.<br>Mentors received 12 hours of training in MI and<br>behavioural strategies to increase physical activity<br>and modify eating. Mentors also received weekly<br>supervision on goal setting and related topics.<br>Parents of adolescents attended monthly parent<br>meetings to discuss progress and build support<br>through education |   |
|-------------------|--|---|
| Sigal 2014        | I1: diet + aerobic training, reduced calorie diet<br>and 4 weekly visits to gym for aerobic training<br>over 22 weeks  | Diet only: reduced calorie diet and usual activity  |
|                   | I2: diet + resistance training: reduced calorie diet<br>and 4 weekly visits to gym for resistance training<br>over 22 weeks  |   |
|                   | I3: diet + aerobic + resistance training: reduced calorie diet and 4 weekly visits to gym for aerobic and resistance training over 22 weeks  |   |
| Love-Osborne 2014 | MI: diet and exercise goal setting, additional text<br>messages for half the group   | Control group, no details   |
| Kong 2014         | Low GI diet individual counselling diet, physical activity and behavioural components. 7 sessions over 6 months  | Usual Chinese diet: individual counselling diet,<br>physical activity and behavioural components. 7<br>sessions over 6 months |
| Luna-Pech 2014    | Normocaloric diet and physical activity, seen ev-<br>ery 2 weeks for 28 weeks  | No intervention, free diet, seen every 2 weeks for 28 weeks   |
| Boodai 2014       | Group sessions focusing on reduction in seden-<br>tary behaviour, diet, promotional of physical ac-<br>tivity  | No intervention, advice to attend primary care  |
| Gourlan 2013      | MI + standard weight loss. Behaviour modifica-<br>tion as well as standard weight loss intervention.<br>No details of number sessions  | Standard weight loss: balanced diet, a healthy lifestyle and physical activity  |
| Patrick 2013      | I1: website intervention. To promote weight loss<br>and healthy behaviours. 51-week intervention,<br>website for adolescents and for parents   | Usual care. Given printed materials   |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 305 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

|               | I2: website + group. To promote weight loss and<br>healthy behaviours. 51-week intervention, web-<br>site for adolescents and for parents. Also group<br>support sessions (number not stated)  |  |
|---------------|--|--|
|               | I3: website + SMS. To promote weight loss and<br>healthy behaviours. 51-week intervention, web-<br>site for adolescents and for parents. Text messages<br>sent weekly  |  |
| Kong 2013     | ACTION. MI, visit to clinician every 2-3 weeks<br>for a total of 8 visits over 1 academic year, DVD<br>toolkit   | Standard care. 1 clinician visit and printed infor-<br>mation  |
| Pbert 2013    | "Lookin' Good Feelin' Good." 6 × 1-on-1 coun-<br>selling sessions conducted over 2 months focused<br>on behavioural change, diet and physical activity<br>goals  | 6 × 1-on-1 visits with the school nurse, informa-<br>tion pamphlets                                  |
| Brennan 2013  | MI. 13 sessions over 4-6 months with or without parent. Then maintenance phase of $2 \times 1$ -hour clinic sessions and $7 \times 15$ -minute maintenance telephone call session and a final face-to-face session 6 months after the last treatment session                       | Wait list control  |
| Walpole 2013  | MI: focus on unhealthy behaviours, 6 sessions, 30-minutes long   | Social skills training: finding ways to navigate so-<br>cial situations, 6 sessions, 30-minutes long |
| Toulabi 2012  | Behavioural modification. Dietary modification<br>and techniques for increasing physical activity. 8<br>$\times$ 45-minute sessions, held twice per week and<br>group physical activity 1 hour per day, 3 days per<br>week, for 6 weeks  | Educational booklets   |
| Debar 2012    | Multicomponent intervention. Group meetings,<br>16 times (90 minutes each) over 5 months for<br>adolescents and 12 sessions for parents  | Usual care. Clinic visit, information and resources  |
| Ebbeling 2012 | Multicomponent intervention. Emphasis on the<br>consumption of sugar-sweetened beverages, pro-<br>vided with written information, telephone calls<br>and 3 check-in visits (20 minutes per visit).<br>Monthly motivational telephone calls with par-<br>ents (30 minutes per call) | Control: no details  |
| Vos 2011      | Family-based CBT + nutrition. Educational ses-<br>sions, computer package, 7 children group meet-<br>ings - 2.5 hours' duration biweekly. 5 parent meet-<br>ings, 1 parent and child meeting   | Wait list control  |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 306 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

| Christie 2011 | Multicomponent motivational and solution-fo-<br>cused family-based weight management pro-<br>gramme. 12 HELP sessions (45 minutes each)<br>across 6 months   | Enhanced standard care, 1 educational session of 40 minutes addressing eating behaviours, healthy activity, uses standard national guidance |
|---------------|--|---|
| Wengle 2011   | I1: mentored lifestyle intervention. Nutrition and activity counselling at baseline, 1, 2, 3 and 6 months. 1-2 hour once per week mentoring sessions to achieve activity goals, participate in physical activity, and discuss and set nutritional goals  | Unmentored lifestyle intervention. Nutrition and activity counselling at baseline, 1, 2, 3 and 6 months                                     |
| Ford 2010     | Mandometer. Real-time feedback during meals to<br>slow down speed of eating and reduce total intake.<br>Weekly visits for 6 weeks, then every 2 weeks for<br>6 weeks then monthly. Telephone support   | Standard care. 3 monthly visits, emphasis on diet<br>and physical activity goal setting   |
| Nguyen 2012   | 11: Loozit + ATC. Healthy lifestyle intervention<br>based on cognitive behavioural approach with an<br>intensive treatment phase followed by a longer<br>maintenance phase. $7 \times 75$ -minute weekly group<br>sessions then $7 \times 60$ -minute sessions over 24<br>months. Telephone coaching, e-mails, text mes-<br>sages (32 electronic and 14 telephone coaching<br>sessions). Adolescent and parent | Loozit as for intervention except no ATC  |
| Grey 2009     | Coping skills. 13 sessions over 16 weeks: 8 nutri-<br>tion and activity classes + 5 coping skill training.<br>Telephone counselling for 9 months   | General education. 8 nutrition and activity classes<br>over 16 weeks  |
| Vissers 2008  | School-based intervention. Physical activity and<br>nutrition sessions and gym membership. 6 nutri-<br>tion sessions: individual or group (maximum of<br>2 group sessions) once per month  | Standard gym classes  |
| NCT00132132   | Behavioural education programme. Monthly 4-<br>hour session which incorporated: exercise, em-<br>powerment, education and incentives   | Standard of care control: education on physical activity and nutrition  |
| Pitetti 2007  | Treadmill. Use of treadmill in usual school activity<br>sessions (3 per week) and also taken to the gym<br>to use the treadmill on days and evenings when<br>not participating in usual school activity sessions   | Usual school activity sessions and Leisure activity of choice   |
| Savoye 2007   | Bright Bodies weight management. Nutrition/<br>behaviour modification once (40 minutes each)<br>per week. Parental involvement in the nutrition<br>related topics. Behaviour modification sessions   | Diet and exercise counselling and brief psy-<br>chosocial counselling. 30 minute session every 6<br>months                                  |

|                          | were held separately for parents and children. At-<br>tended twice per week for 6 months and then ev-<br>ery other week for an additional 6 months   |   |  |  |
|--------------------------|--|---|--|--|
| van Egmond-Frohlich 2006 | Multicomponent intervention: after a rehabilita-<br>tion programme participating physicians of the<br>intervention group received a practice guideline:<br>this addressed the guilt or fate problem, treatment<br>aims (health promotion activities), guidance on<br>fat-limiting mixed diet, promotion of a physical<br>active lifestyle, local support resources, promo-<br>tion of flexible control of eating and patient guid-<br>ance according to the public health counselling<br>and self-management model<br>The outpatient programme was intended to have<br>health check-ups every 4 weeks during the first<br>12 months (10-12 appointments) | Standard care   |  |  |
| Daley 2005               | Exercise counselling. 8 weekly behavioural ses-<br>sions focused on attitudes to exercise. Offered aer-<br>obic exercise modalities, asked to exercise inter-<br>mittently for 30 minutes, 3 times per week for 8  | C1: exercise placebo. 24 sessions over 8 weeks;<br>performed light body-conditioning/stretching<br>exercises<br>C2: usual care  |  |  |
| Resnicow 2005            | weeks<br>Go Girls. High intensity. Weekly (20-26) be-<br>havioural sessions. 1 meeting/week for 6 months<br>(parents attending 10-13 times), 1 day retreat, 6<br>MI telephone calls. 2-way paging messages to sup-<br>port behavioural change. Retreats (unclear how<br>many)  | Moderate intensity 6 sessions over 6 months (1<br>per month), parents attending 3. Sessions were<br>selected from the larger pool of sessions delivered<br>to the intervention group  |  |  |
| Jiang 2005               | Family-based intervention. 104 weeks (2 years).<br>Unclear number of sessions  | Usual care  |  |  |
| Carrel 2005              | Lifestyle-focused gym classes. Fitness-oriented<br>group gym classes, movement time was 42 min-<br>utes of a 45-minute class period. 36- week (9<br>month) intervention, 90 sessions   | Standard gym classes. 36-week (9-month) inter-<br>vention, 90 sessions (5 times every 2 weeks for a<br>45-minute class period), Movement time 25 min-<br>utes of the 45-minute period |  |  |
| Ebbeling 2003            | Low GL diet. 12 sessions over 6 months (12 di-<br>etary counselling sessions) and a 6-month follow-<br>up (2 dietary counselling sessions)   | Conventional low-fat diet. 12 sessions over 6-<br>months (12 dietary counselling sessions) and a 6-<br>month follow-up (2 dietary counselling sessions)                               |  |  |
| Saelens 2002             | Healthy Habits. Computer- and telephone-deliv-<br>ered intervention, focus on diet and physical ac-<br>tivity goals, 1 tailored physician-counselling ses-<br>sion. 12 telephone call sessions with counsellor<br>(10-20 minutes). Overall duration was 16 weeks<br>with 13 sessions   | Standard care. Non-tailored physician-coun-<br>selling session  |  |  |

<sup>a</sup>Clear that outcome was measured and analysed; trial report states that outcome was analysed but reports only that result was not significant

(Classification 'A', table 2, Kirkham 2010)

<sup>b</sup>Clear that outcome was measured and analysed; trial report states that outcome was analysed but report no results

(Classification 'D', table 2, Kirkham 2010)

<sup>c</sup>Clear that outcome was measured but was not necessarily analysed; judgement says likely to have been analysed but not reported because of non-significant results

(Classification 'E', table 2, Kirkham 2010)

<sup>d</sup> Unclear whether outcome was measured; not mentioned, but clinical judgement says likely to have been measured and analysed but not reported on the basis of non-significant results

(Classification 'G', table 2, Kirkham 2010)

### Appendix 9. Checklist to aid consistency and reproducibility of GRADE assessments

|  |  | Changes in BMI, BMI<br>z score, body weight | Adverse events | Health-related quality of life |
|--|--|---|----------------|--------------------------------|
| Study limitations<br>(risk of bias) <sup>a</sup> | 1. Was random sequence<br>generation used (i.e. no<br>potential for selection<br>bias)?  | Yes   | Yes            | Yes                            |
|  | 2. Was allocation con-<br>cealment used (i.e. no<br>potential for selection<br>bias)?  | Unclear                                     | Unclear        | Unclear                        |
|  | 3. Was there blinding of<br>participants and person-<br>nel (i.e. no potential for<br>performance bias)?                                       | No  | Unclear        | No ()                          |
|  | 4. Was there blinding of<br>outcome assessment (i.e.<br>no potential for detec-<br>tion bias)?   | No  | Unclear        | No                             |
|  | 5. Was an objective out-<br>come used?   | Yes   | Unclear        | No                             |
|  | 6. Were x 80% of par-<br>ticipants enrolled in tri-<br>als included in the anal-<br>ysis (i.e. no potential re-<br>porting bias)? <sup>e</sup> | Yes   | No ()          | Yes                            |

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 401 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

|                            | 7. Were data reported<br>consistently for the out-<br>come of interest (i.e.<br>no potential selective re-<br>porting)?   | Yes                          | No () | No (some studies did not re-<br>port health-related quality of<br>life despite mentioning) |
|----------------------------|---|------------------------------|-------|--|
|                            | 8. No other biases reported (i.e. no potential of other bias)?  | Yes                          | No () | Yes  |
|                            | 9. Did the trials end<br>up as scheduled (i.e. not<br>stopped early)?   | Yes                          | Yes   | Yes  |
| Inconsistency <sup>b</sup> | 1. Point estimates did<br>not vary widely?  | No (some variability)        | N/A   | Yes  |
|                            | 2.<br>To what extent did con-<br>fidence intervals over-<br>lap (substantial: all confi-<br>dence intervals overlap at<br>least one of the included<br>studies point estimate;<br>some: confidence inter-<br>vals overlap but not all<br>overlap at least one point<br>estimate; no: at least one<br>outlier: where the confi-<br>dence interval of some of<br>the studies do not over-<br>lap with those of most in-<br>cluded studies)? | Some                         | N/A   | Some   |
|                            | 3. Was the direction of effect consistent?  | Yes                          | N/A   | Yes  |
|                            | 4. What was the mag-<br>nitude of statistical het-<br>erogeneity (as measured<br>by $I^2$ ) - low ( $I^2 < 40\%$ ),<br>moderate ( $I^2 40\%$ -60%)<br>, high $I^2 > 60\%$ )?  | High ()                      | N/A   | High ()  |
|                            | 5. Was<br>the test for heterogeneity<br>statistically significant (P<br>< 0.1)?   | Statistically significant () | N/A   | Statistically significant ()   |

| 3. Were no restrictions<br>applied to study selec-<br>tion on the basis of lan-<br>guage?        | Yes     | Yes     | Yes     |
|--|---------|---------|---------|
| 4. There was no industry<br>influence on studies in-<br>cluded in the review?                    | Yes     | Yes     | Yes     |
| 5. There was no evidence<br>of funnel plot asymme-<br>try?                                       | Unclear | N/A     | Unclear |
| 6. There was no dis-<br>crepancy in findings be-<br>tween published and un-<br>published trials? | Unclear | Unclear | Unclear |

 $^{a}$  Questions on risk of bias were answered in relation to the majority of the aggregated evidence in the meta-analysis rather than to individual studies.

 $^{b}$ Questions on inconsistency were primarily based on visual assessment of forest plots and the statistical quantification of heterogeneity based on I<sup>2</sup>.

<sup>c</sup>When judging the width of the confidence interval it was recommended to use a clinical decision threshold to assess whether the imprecision was clinically meaningful.

<sup>d</sup>Questions addressed comprehensiveness of the search strategy, industry influence, funnel plot asymmetry and discrepancies between published and unpublished trials.

<sup>e</sup>Depended on the context of the systematic review area.

(): key item for potential downgrading the quality of the evidence (GRADE) as shown in the footnotes of the 'Summary of finding' table

BMI: body mass index; N/A: not applicable.

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Given the rapid growth in the treatment of child and adolescent obesity, the original review was split into six separate reviews, with a specific intervention and age focus.

- Diet, physical activity and behavioural interventions for the treatment of overweight or obesity in adolescents aged 12 to 17 years.
- Diet, physical activity and behavioural interventions for the treatment of overweight or obesity in children aged 5 to 11 years.
- Diet, physical activity and behavioural interventions for the treatment of overweight or obesity in infants aged 0 to 4 years.
- Drug interventions for the treatment of obesity in children and adolescents.
- Parent-only interventions for childhood overweight or obesity.
- Surgery for the treatment of obesity in children and adolescents.

For behaviour changing interventions, we included only randomised controlled trials that were specifically designed to treat obesity in children and observed participants for a minimum of six months. The rationale for introducing this criterion arose from the belief that many interventions appear to be effective in the short term (up to three months), but not in the long term (Glenny 1997). It seemed to be more important to evaluate the longer-term effects of treatments, as this would provide a more valuable indication of effectiveness, given the chronic nature of obesity.

We did not present prediction intervals as originally described for the suite of reviews for consistency as the other reviews did not do this either in consultation with the review group.

We did not perform the following sensitivity analyses.

Diet, physical activity and behavioural interventions for the treatment of overweight or obese adolescents aged 12 to 17 years (Review) 420 Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd. • Restricting the analysis taking into account risk of bias, as specified in the section Assessment of risk of bias in included studies section, but we did look at the effects of attrition bias and other potential bias introduced by analysis of cluster randomised controlled trials.

- Restricting the analysis to very long or large studies to establish how much they dominated the results.
- Restricting the analysis to studies using the following filters: diagnostic criteria, funding source and country.

This is in line with other reviews in this series.

## ΝΟΤΕS

Part of the background, the methods section, appendices, additional tables and figures 1 to 3 of this review are based on a standard template established by the Cochrane Metabolic and Endocrine Disorders Group.
