#### 30 ABSTRACT

- 31 **Context.** Prolonged adrenal stimulation by corticotropin, as in long-standing Cushing's disease (CD),
- 32 leads to diffuse to nodular hyperplasia. Adrenal functional autonomy has been described in a subset of
- 33 patients with CD, leading to the hypothesis of transition from ACTH-dependent to ACTH-independent
- 34 hypercortisolism.
- 35 **Objective.** Considering that *PRKACA* somatic mutations are the most common finding in adrenal
- 36 adenomas associated with ACTH-independent Cushing's syndrome, our aim was to analyze PRKACA
- 37 mutations in adrenals of patients with persistent/long-standing CD.
- 38 **Design.** Cross-sectional.
- **Setting.** University hospital.
- 40 Patients. Two patients with long-standing CD and suspicion of coexistence of autonomous adrenal
- 41 hyperfunction, according to pre- and postoperative evaluations, were selected for this study following
- 42 intensive literature search and patient chart reviewing.
- 43 Intervention. Clinical data were analyzed. DNA was extracted from adrenal tissue for *PRKACA*44 sequencing. PKA activity was assayed.
- 45 Main outcome measure. *PRKACA* somatic mutations.
- 46 **Results.** Both patients showed mutations of *PRKACA* in macronodule in the context of micronodular 47 adrenal hyperplasia. One patient harbored the previously described p.Leu206Arg substitution, whereas 48 a p.Ser213Arg missense variation was detected in the adrenal nodule of the second patient. No 49 mutations were detected in the adjacent adrenal cortex of the second patient. In silico analysis predicts 50 that p.Ser213Arg can interfere with the interaction between the regulatory and catalytic subunits of 51 PKA.
- 52 **Conclusions.** Our study shows that *PRKACA* somatic mutations can be found in adrenal nodules of 53 patients with CD. These genetic alterations could represent a possible mechanism underlying adrenal 54 nodule formation and autonomous cortisol hyperproduction in a subgroup of patients with long-55 standing CD.

## 84 Introduction

Prolonged hyperstimulation by ACTH results in alterations of adrenal gland architecture that range 85 from diffuse hyperplasia to micro- and macronodules (1, 2), driven by the trophic effects of 86 corticotropin. Those morphological changes are a common feature of adrenals of patients with long-87 standing Cushing's disease (CD). According to several previous reports (3-11), the occurrence of 88 nodules in the context of ACTH-stimulated adrenal hyperplasia has been associated with variable 89 90 degrees of functional adrenal autonomy, leading to the hypothesis that transition from ACTHdependent to ACTH-independent hypercortisolism could indeed occur in a subgroup of patients with 91 92 long duration of the disease.

93 In the last years, the molecular mechanisms of ACTH-independent hypercortisolism have been 94 extensively investigated in several independent cohorts (12-19). The results of these studies showed 95 that somatic mutations in the gene encoding the catalytic  $\alpha$  (C $\alpha$ ) subunit of protein kinase A (PKA) 96 (*PRKACA*), leading to constitutive PKA activation, are a common finding in patients with Cushing's 97 syndrome due to adrenal adenoma.

98 The aim of our study was to analyze *PRKACA* mutations in adrenal glands of patients with 99 persistent/long-standing CD and suspected coexistence of adrenal autonomy, to test whether the gain 100 of function by the adrenal nodules can be driven by constitutive PKA activation.

101

#### **102** Materials and Methods

#### 103 Patients and clinical data

We enrolled two patients who were referred for severe hypercortisolism to two European centers: Department of Internal Medicine, Nijmegen, The Netherlands (patient 1) and Endocrinology Division, Ancona, Italy (patient 2). Patients were selected based on the clinical history, according to the following inclusion criteria: (i) diagnosis of Cushing's disease due to pituitary adenoma, (ii) suspected coexistence of autonomous adrenal hyperfunction, according to pre- and postoperative evaluation, (iii) trans-sphenoidal surgery, (iv) recurrence or persistence of the disease without evidence of pituitary remnant, and (v) histological evidence of adrenal hyperplasia with and without nodules. The medical history of patient 1 has been already published elsewhere (4). Detailed clinical and preoperativehormonal data were collected for patient 2 by reviewing the medical charts.

All patients gave written informed consent for genetic analysis. The study was approved by the ethicscommittee of the individual institutions.

115

116 DNA extraction, sequencing, and in silico analysis

Formalin-Fixed Paraffin Embedded (FFPE) (patient 1) and fresh-frozen (patient 2) adrenal tissues were employed for DNA extraction. The DNA was selectively extracted from the macronodules after a careful microdissection of the tumoral area performed by experienced pathologists (B.K. for patient 1, and M.S. for patient 2). In patient 2, adrenal tissue adjacent to nodular area was also available for DNA extraction.

Genomic DNA was extracted with QIAmp® DNA FFPE tissue kit (Qiagen, Hilden, Germany) in 122 FFPE tissue, and Maxwell® Blood DNA Kit (Promega Corp., Madison, WI) in frozen tissues. DNA 123 was amplified by PCR (details are provided in supplementary material). Bidirectional Sanger 124 125 sequencing was performed using the ABI BigDye Terminator v.3.1 Cycle Sequencing Kit. The results of the sequencing analysis were evaluated using the Mutation Surveyor software (SoftGenetics). The 126 results were confirmed after a second DNA extraction. Images of *in silico* analysis were prepared 127 128 using the PyMOL software (www.pymol.org). The structure of the mouse full-length tetrameric 129 RII $\beta(2)$ :C $\alpha(2)$  holoenzyme (PDB entry 3TNP) (20) was used to display the PKA C $\alpha$  and regulatory 130 subunit (RII $\beta$ ) structures.

131

#### 132 *PKA activity assay*

HEK293A cells were seeded at a density of 0.25 x 106 cells/well onto 6-well plates and allowed to
grow for 24 h, before transfection with Effectene (Qiagen) according to the manufacturer's
instructions. Catalytic and regulatory subunits were co-transfected in a 1:8 ratio. All experiments were
performed 48 h after transfection.

Cells were washed twice with phosphate-buffered saline at room temperature, 300 µl lysisbuffer (5 137 mM Tris-HCl, 2 mM EDTA, pH 7.4) were added and cells were scraped from the plate. Lysis was 138 139 done using an Ultraturrax for 20 s on ice. Then samples were centrifuged at 50,000 x g for 30 min at 4°C to remove membranes. PKA subunit Ca RIIB expression in cell lysates were determined by 140 Western blotting with specific antibodies (anti-PKA Ca (1:7000), #4782, Cell Signaling Technology; 141 anti-PKA RIIB (1:1000), #610625, BD Transduction Laboratories), to use equal amounts of catalytic 142 143 subunit for the PKA activity assay. PKA catalytic activity was measured with or without the addition of cyclic AMP (cAMP) using the PepTag non-radioactive cAMP-dependent protein kinase assay 144 (Promega), following the manufacturer's instructions. Images were acquired using a gel 145 documentation system (Herolab) and analyzed with ImageJ software (http://rsbweb.nih.gov/ij). 146 Activity of endogenously expressed PKA was subtracted and samples were normalized to expression 147 levels of PKA Ca. Data are mean±s.e.m. of three independent experiments (two replicates per 148 experiment). 149

150

151 Statistical analysis

Statistical analysis was done using Graphpad Prism 6. Results are shown as mean±SEM. Statistical
analysis was performed using 2-way ANOVA followed by Bonferroni's post-hoc test to correct for
multiple comparisons.

155

156 **Results** 

157 The clinical history and the preoperative hormonal evaluation of the two patients are summarized in158 Table 1.

159

160 Patient 1

161 The clinical history of this patient has already been described (4). This 41-years old woman was 162 referred to the Department of Internal Medicine of Radboud University Medical Center of Nijmegen 163 (The Netherlands) in 2002 for clinical hypercortisolism, confirmed by elevated cortisol levels after 1-

mg dexamethasone suppression test (DST), high urinary free cortisol (UFC) and midnight cortisol 164 values. The results of CRH testing and high-dose DST were atypical for ACTH-dependent 165 166 hypercortisolism. However, basal ACTH was elevated, and the pituitary MRI showed a left pituitary microadenoma (7 mm). The inferior petrosal sinus sampling was indicative of a central source of 167 ACTH. The patient underwent trans-sphenoidal surgery with removal of the pituitary microadenoma, 168 confirmed by histological examination (positive ACTH staining). After surgery, the patient 169 170 experienced clinical remission and normalization of UFC and morning cortisol levels. However, cortisol after 1-mg DST was still elevated. An abdominal CT-scan revealed a left adrenal 171 macronodule. During the 12 months following surgery, the patient experienced recurrence of signs 172 specific to hypercortisolism. Increase in UFC levels with undetectable ACTH were also recorded. The 173 pituitary MRI at that time was unremarkable. The patient underwent left adrenalectomy and 174 histological examination showed a 35-mm macronodule in the context of focal micronodular 175 hyperplasia. Glucocorticoid replacement therapy was needed for one year after surgery. At the last 176 follow-up, 15 years after surgery, the patient was free of recurrence. 177

Analysis of the left adrenal macronodule showed a c.617A>C (p.Leu206Arg) missense mutation. No
adjacent adrenal cortex was available for genetic screening. The functional implications of this
mutation have previously been described (13).

181

# **182** *Patient 2*

This patient, a 31-years old woman, was referred to the Endocrinology division of Ancona (Italy) in 183 2000 for clinical Cushing's syndrome developed during the last 28 months. UFC and midnight cortisol 184 levels were indicative of hypercortisolism, which was confirmed by the cortisol levels after 1-mg 185 186 DST. Basal ACTH and stimulation tests with CRH and desmopressin were concordant with the 187 diagnosis of CD. Cortisol level after high-dose DST was 166 nmol/L. A pituitary MRI-scan revealed a microadenoma. The patient was treated with trans-sphenoidal surgery and histological examination 188 confirmed an ACTH-positive pituitary microadenoma. After surgery, the patient experienced 189 persistence of clinical and biochemical hypercortisolism, accompanied by undetectable plasma ACTH 190

levels and no evidence of remnant adenoma at pituitary MRI. An abdominal CT-scan showed bilateral
diffuse enlargement with a left-sided adrenal nodule. Two years after surgery, bilateral adrenalectomy
was performed. Histological examination showed a left macronodule in the context of micronodular
hyperplasia.

PRKACA analysis showed a missense mutation c.639G>T (p.Ser213Arg) in tissue extracted from the 195 adrenal macronodule. No mutations were found in the adjacent hyperplastic tissue, supporting the 196 197 concept that the mutation occurred at a somatic level. As depicted in Figure 1, in silico analysis of the 198 mutation showed that Ser213 is located at the surface of the C $\alpha$  subunit of PKA, in a region that adopts a "tip-like" structure, which is inserted into a complementary cavity of the regulatory subunit. 199 200 Substitution with an arginine in position 213 could therefore impede the interaction between the regulatory and catalytic subunits, leading to unregulated activation of the latter. As shown in Figure 2, 201 202 a PKA activity assay revealed that mutant cells expressing Ca subunit with Ser213Arg missense 203 mutations had higher basal PKA activity than cells transfected with WT C $\alpha$  subunit, in the absence of 204 cAMP. The high basal PKA activity was not different from Leu206Arg mutation (Figure 2).

205

# 206 Discussion

In a subgroup of patients with CD, the progressive acquisition of functional autonomy by the adrenals has been claimed as a potential evolution of the natural history of the disease. The so-called "transition" from pituitary to adrenal hypercortisolism in CD is supposed to be a late feature of the disease that occurs mainly in the presence of nodular alterations of the adrenal gland. However, until now, this entity has been hypothesized only based on clinical and biochemical features, given that no studies have yet investigated the molecular mechanisms underlying this condition.

In this study, we screened *PRKACA* mutations in two patients carefully selected on the basis of ambiguous pre- and post-operative evaluations indicative of hypercortisolism of adrenal as well as pituitary origin. We aimed to test the hypothesis whether the acquisition of adrenal autonomy, presumed by the hormonal tests, can be driven by a gain of function of PKA. In fact, it is now well known that *PRKACA* somatic mutations, which lead to autonomous activation of PKA, are the underlying cause of ACTH-independent hypercortisolism in more than 30% of patients with adrenaladenomas (12-19).

220 The adrenals of the two patients enrolled in this study showed somatic PRKACA mutations. 221 Specifically, we found a p.Leu206Arg substitution in one patient (n. 1), which is the most frequent alteration in ACTH-independent Cushing's syndrome, and a p.Ser213Arg substitution in the second 222 one (n. 2). The p.Ser213Arg substitution has been already described in a recent study, in association 223 224 with a 12-bp duplication, in a patient with adrenal Cushing's syndrome (16). According to functional 225 and *in silico* analysis, those mutations impede the interaction between C $\alpha$  and the regulatory subunit of PKA by altering the structure of the former, causing a cAMP-independent increase in PKA activity 226 227 (21, 22). The *in silico* analysis of the p.Ser213Arg substitution predicted a similar pathogenetic 228 mechanism, even though no functional analysis was performed to confirm this hypothesis. Nonetheless, with respect to WT, the p.Ser213Arg missense mutation showed high basal PKA 229 activity, similar to the known p.Leu206Arg mutation. Those data suggest a pathogenetic role also for 230 this novel variant in inducing PKA activation. 231

232 The discovery of PRKACA somatic mutations in adrenals of a specific subset of patients with CD is novel and provides indirect evidence for the concept of an evolutionary transition from pituitary-233 dependent to adrenal-dependent hypercortisolism, sustained by the acquirement of PKA autonomous 234 235 activity. The exact mechanism that leads to this entity is unknown. It is tempting to speculate that the 236 continuous growth stimulation and the prolonged activation of steroidogenesis exerted by corticotropin could generate a favorable microenvironment that facilitates the onset of genetic 237 aberrations resulting in adrenal nodularity. The higher sensitivity to ACTH of adrenal nodules 238 239 compared to the hyperplastic adjacent cortex in CD, previously demonstrated in *in vitro* and *in vivo* 240 studies (3, 7, 23, 24), could be a contributing factor. If true, it is feasible that those conditions may be 241 associated with a more severe hypercortisolism than patients with Cushing's disease, even though this should be investigated in targeted studies. However, given the rarity of the occurrence of transition 242 from pituitary- to adrenal-dependent Cushing's syndrome, the coexistence of autonomous pituitary 243

and adrenal masses sustained by independent genetic events cannot be ruled out and should be furtherinvestigated.

In summary, this study shows that *PRKACA* somatic mutations can be found also in adrenal nodules of a subset of patients with CD, in specific conditions such as long duration of hypercortisolism and nodular alterations of the adrenal gland. These findings provide important insights into the pathophysiology of adrenal gland hyperplasia in CD.

327 Figure legends

#### 328 Figure 1. In silico analysis of the Ser213Arg missense mutation.

The figures focus on the region of the catalytic subunit (green) of PKA that adopts a "tip-like" structure, which is inserted into a complementary cavity of the regulatory subunit (red). The upper part of the figure shows the wild-type situation in stick mode (A) and in space-filling representation (B), with serine in position 213 (arrow). In the lower part of the figure, the *in silico* replacement of arginine at position 213 in one possible conformation (arrow) is represented in stick (C) and space-filling (D) mode. Substitution of the serine with an arginine at position 213 is thus likely to cause steric hindrance, which is expected to interfere with the association between the two subunits of PKA.

336

#### 337 Figure 2. PKA activity assay of the Ser213Arg missense mutation.

338 A. The Figure shows the PKA activity against a synthetic peptide substrate (kemptide). HEK293A 339 cells were co-transfected with RII $\beta$  and either wild-type (WT) or mutant (L206R, S213R) Ca 340 subunits. PKA activity in cell lysates was then measured under basal condition or upon stimulation with cAMP (40 µM). The PKA activity measured in cells transfected with the empty expression vector 341 342 (pcDNA) was subtracted. Data are mean±s.e.m. of three independent experiments. Data are statistically significant by two-way ANOVA. \*P<0.05. \*\*P<0.01 vs. WT basal by Bonferroni's post 343 hoc test. **B.** The upper part of the figure shows data (mean±s.e.m.) of all three experiments, as shown 344 345 in A, without subtraction of the endogenous PKA activity. In the lower part of the figure, a representative Western blot of a single experiment, showing similar expression levels of RIIB and the 346  $C\alpha$  subunits in the samples, is depicted. 347
