## Abstract

Bilingualism and its cognitive impacts have drawn increasing interest. Recently, inconsistencies in the findings have raised discussions on what might have caused such discrepancies and how evidence should be evaluated. This review tries to shed new light onto the reasons for the inconsistencies by taking a novel perspective. Motivated by the finding that bilingualism affects response time distribution profiles, particularly findings that suggest bilinguals have fewer long responses, we investigated the relation between maximum response times allowed/included in the analysis of an experiment and the finding of a bilingual advantage. We reviewed 68 experiments from 33 articles that compared monolingual and bilingual speakers' performance in three commonly used non-verbal interference tasks (Simon, Spatial Stroop and Flanker). We found that studies that included longer responses in their analysis were more likely to report a bilingualism effect. We conclude that seemingly insignificant details such as the data trimming procedure can have a potential impact on whether an effect is observed. We also discuss the implication of our findings and suggest the usefulness of more fine-grid analytical procedures.

Recent years have seen an ever-increasing interest in bilingualism, especially in how the bilingual experience leads to cognitive changes (Kroll & Bialystok, 2013). One of the key discoveries was the finding that the two languages of a bilingual speaker are always active, even if the speaker is using only one language in a particular situation (BijeljacBabic, Biardeau, & Grainger, 1997; Colome, 2001; Spivey & Marian, 1999; Wu & Thierry, 2010). Therefore, bilingual experience requires that the speaker constantly monitors and controls language choice. But the soaring interest in bilingualism rather stems from reports that the constant demand on control processes appears to lead to a bilingual cognitive control advantage (for a review see Bialystok, 2009). Possibly the most exciting finding was that the onset of dementia appears to be later for bilingual speakers than for monolingual speakers (Alladi et al., 2013; Bialystok, Craik, & Freedman, 2007), suggesting that bilingualism provides a cognitive reserve. Another reason for the interest in bilingualism is the fact that evidence regarding the bilingual cognitive advantage is inconclusive. Quite a large number of studies have reported a bilingual advantage in cognitive control. But recent developments in the field have suggested that the evidence concerning the bilingual advantage, especially in non-verbal inhibition tasks, is far from conclusive (Hilchey & Klein, 2011; Paap, 2014; Paap & Greenberg, 2013).

### **Evidence for and against bilingual advantage**

Early studies investigating speakers' cognitive control abilities have reported a bilingual advantage. These studies utilized the Simon task (Simon & Rudell, 1967), a task

1  
2  
3 in which participants have to respond to a stimulus feature (e.g. respond according to the  
4 colour of a stimulus, left hand for red, and right hand for blue). The position of the  
5 stimulus could be either compatible or incompatible with the response hand. In this  
6 paradigm, responses are typically slower when stimulus position and response hand are  
7 incompatible. Bilingual speakers outperformed monolingual speakers in this task: they  
8 showed smaller stimulus congruency effects and/or overall faster response times  
9 (Bialystok, Craik, et al., 2005; Bialystok, Craik, Klein, & Viswanathan, 2004; Bialystok,  
10 Martin, & Viswanathan, 2005). Using other variants of the Simon task (e.g., Spatial  
11 Stroop task, Bialystok, 2006) or paradigms that also require interference  
12 inhibition/conflict resolution (e.g., Flanker task, Eriksen & Eriksen, 1974), such bilingual  
13 advantage over monolingual performance has been reported many times over the years  
14 since the first report (e.g. Costa, Hernandez, Costa-Faidella, & Sebastian-Galles, 2009;  
15 Costa, Hernandez, & Sebastian-Galles, 2008; Kapa & Colombo, 2013; Tao, Marzecova,  
16 Taft, Asanowicz, & Wodniecka, 2011).

But the evidence is not consistent. While a bilingual advantage is often found, this is not always the case (for a review see Hilchey & Klein, 2011). Most strikingly, in a recent comprehensive study, Paap and Greenberg (2013) did not find any evidence for the bilingual advantage. They conducted a series of non-verbal conflict tasks that had commonly been used in previous studies, including the Simon task, with monolingual and bilingual college students. Bilingual speakers were neither less vulnerable in the conflict condition nor faster overall. On the contrary, the only group difference pointed to a bilingual disadvantage.

These inconsistent findings have raised serious discussions about the nature of the bilingualism effect and thought-provoking debates on how the evidence should be evaluated (e.g. Kroll & Bialystok, 2013; Paap, 2014; Valian, 2015). Several reviews have drawn attention to the published and non-published null results regarding the bilingualism effect, arguing that one should not over-evaluate the significance of positive findings, and should not under-evaluate the meaning of null results. Others discussed methodological issues (Paap, Johnson, & Sawi, 2015), such as the appropriateness of using covariates to control for additional factors, and the convergent validity of tasks used to measure executive control, i.e. the lack of significant correlations between standard measures of inhibition. The series of discussions provided a great chance to reflect on the current status in this research field, and more importantly on where the field is heading. Bearing that in mind, one constructive way to enhance our understanding of the consequences of bilingualism is to understand what factor(s) drives the divergence of results. The focus of this article is to contribute to the discussion from a novel perspective, i.e. the impact of seemingly trivial data trimming procedures.

### **Factors that potentially drive the inconsistency**

In order to shed light onto the reasons for the inconsistencies in the literature, it is important to understand how other factors might interact with speakers' cognitive control ability. Quite a number of factors have been pointed out. It was evident from the beginning that bilingual research is challenging due to the diversity of speakers' linguistic profiles and experiences (Bialystok, 2001; Grosjean, 1998). Depending on their life experience, one bilingual speaker can differ from another one in many ways. Such

1  
2  
3 heterogeneity in linguistic experiences has been shown to have led to diverse cognitive  
4  
5 consequences, such as level of language proficiency (e.g. Mishra, Hilchey, Singh, &  
6  
7 Klein, 2012), stage of second language acquisition (early bilingual VS late bilingual,  
8  
9 Kalia, Wilbourn, & Ghio, 2014), the degree of bilingualism (dominant VS balanced  
10  
11 bilingual, Goral, Campanelli, & Spiro, 2015), pattern of language use, varying experience  
12  
13 with frequent language switch (Soveri, Rodriguez-Fornells, & Laine, 2011), the similarity  
14  
15 between a bilingual speakers' two languages (Coderre & van Heuven, 2014) and  
16  
17 multilingualism (Poarch & van Hell, 2012). In addition, there are factors that are closely  
18  
19 related to bilingualism or factors that drive the different language experiences, which at  
20  
21 the same time are related to general cognitive performances. These include social and  
22  
23 economic status (Morton & Harper, 2007), different cultural backgrounds (Yang, Yang,  
24  
25 & Lust, 2011) and immigration status. Last but not least there are factors that affect one's  
26  
27 general executive functioning and that probably affect monolingual and bilingual  
28  
29 speakers in the same way, such as age, education, exercise, music training, active video  
30  
31 game experience and others (for an overview see Valian, 2015). These latter factors  
32  
33 emphasize that cognitive control can be trained in other ways than by being bilingual and  
34  
35 that the populations of monolinguals and bilinguals can substantially overlap with regards  
36  
37 to their performance in cognitive tasks. Such an overlap would also explain why the  
38  
39 bilingualism effect has not been found in every study.

## 52 **A new proposal**

53  
54  
55 Another reason for the inconclusiveness of the literature might be the nature of  
56  
57 the bilingual cognitive effect, which is better described as a mixture of effects rather than  
58  
59  
60

1  
2  
3 a single one. For instance, Hilchey and Klein (2011) differentiated between two patterns  
4 of bilingual advantage, namely an inhibitory control advantage (i.e. bilinguals showing a  
5 reduced conflict effect) and an overall response speed advantage. This distinction  
6 suggests two routes through which bilingual experience could affect cognitive control:  
7 inhibitory control and attentional control. While enhanced inhibitory control ability  
8 should help to resolve conflict, resulting in a reduced conflict effect, enhanced attentional  
9 control should help to maintain task goals, leading to an overall speed advantage. Due to  
10 the general impurity of cognitive control tasks, a specific task does not provide a pure  
11 measure of a single control ability, but draws on many aspects of cognitive control. Some  
12 tasks might be more sensitive to participants' inhibitory control ability and some to their  
13 attentional control ability. Therefore depending on the task, one might observe a result  
14 pattern rather consistent with a bilingual inhibitory control advantage and/or bilingual  
15 attentional control advantage.

32  
33

34 Tse and Altarriba (2012) utilized a novel analytical approach to the bilingual  
35 advantage effect. They performed an ex-Gaussian analysis to investigate response time  
36 distributions of bilingual speakers' performance in a Colour Stroop task. Response times  
37 in cognitive experiments typically present themselves in a positively skewed distribution,  
38 which can be approximated by an ex-Gaussian distribution (Heathcote, Popiel, &  
39 Mewhort, 1991), i.e. a convolution of a Gaussian distribution (the mean of which is  
40 captured by the parameter  $\mu$ ) and an exponential distribution (the mean and variance of  
41 which are captured by the parameter  $\tau$ ). While the Gaussian component (the parameter  $\mu$ )  
42 can be understood as the main body of the distribution, the exponential component (the  
43 parameter  $\tau$ ) captures the tail of the distribution, i.e. extremely slow responses. Tse and  
44

1  
2  
3 Altarriba (2012) suggested that the parameters of ex-Gaussian models of response time  
4 distributions in a Colour Stroop experiment are differentially sensitive to inhibitory  
5 control and attentional control. They argued that inhibitory control ability modulates the  
6 Gaussian component ( $\mu$ ) because differences in inhibitory control would affect the ease  
7 one resolves the competition between the two conflicting responses, leading to an overall  
8 shift of the response distribution in the conflict condition as compared to the no-conflict  
9 condition. In contrast, attentional control ability modulates the tail of the distribution ( $\tau$ )  
10 because lapses of attention should lead to extreme long responses independent of  
11 condition. They found that more proficient speakers in L1/L2 showed a smaller  
12 interference effect in  $\mu$ , and also smaller  $\tau$  independent of condition. This result is  
13 important, first because it proposes a way to disentangle the contribution of inhibitory  
14 and attentional control, and second because it suggests that what is usually treated as  
15 unwanted responses ( $\tau$ ) conveys important information.

31  
32  
33

34 One other study that has utilized the ex-Gaussian approach to examine response  
35 time distributions is Calabria, Hernandez, Martin, and Costa (2011). They re-analyzed  
36 results from an Attentional Network Task (ANT) originally reported in Costa et al.  
37 (2008) and Costa et al. (2009). In the original studies, they tested participants' attentional  
38 networks using the ANT, which generates measurements for three attentional networks:  
39 an alerting network, an orienting network and an executive network. In their re-analysis,  
40 they focused on the executive network, or more specifically, on response times for trials  
41 with conflict stimuli versus trials with non-conflict stimuli (regardless of cue type).  
42 Results revealed an overall speed advantage for bilinguals in both the Gaussian ( $\mu$ ) and  
43 exponential ( $\tau$ ) components of the response distributions. Also, for an experiment that  
44  
45  
46  
47  
48  
49

54  
55  
56  
57  
58  
59  
60

1  
2  
3 contained only 25% inconsistent trials, i.e. under high monitoring demands, monolinguals  
4  
5 had significant longer distribution tails (larger  $\tau$ ) in the incongruent compared to the  
6  
7 congruent condition. This congruency effect was absent for bilinguals. These results  
8  
9 suggest that the conflict effect in interference tasks is at least partially located in the tail  
10  
11 of response distributions.  
12  
13

14  
15 These observations lead to a new proposal that we investigated in the present  
16  
17 study, namely that one reason for observing or not observing the bilingual advantage  
18  
19 might be how the data was handled with regards to slow responses. In a traditional central  
20  
21 tendency analysis, the typical procedure is to trim extreme responses, treating them as  
22  
23 outliers. This is problematic if long responses are most sensitive to the experimental  
24  
25 manipulation and/or group differences, as in studies where group/condition differences  
26  
27 only emerged in the tail of response distributions (e.g. Epstein et al., 2011; Hervey et al.,  
28  
29 2006). In other words, if a difference resides in the tail of the response distribution, by  
30  
31 trimming the tail one also trims the potential to observe an effect. For instance, Leth-  
32  
33 Steensen, Elbaz, and Douglas (2000) investigated response time distributions in a four-  
34  
35 choice reaction time task for a group of children diagnosed with ADHD and a matched  
36  
37 group with typical developing children. Using an ex-Gaussian analysis, they found that  
38  
39 the two groups' performances differed only in the  $\tau$  parameter (the distribution tails), not  
40  
41 in the main part of the response time distribution. The authors concluded that data  
42  
43 trimming in this situation is equivalent to an artificial elimination of effects.

60

1  
2  
3  
4 In what follows, we present a new perspective on previous studies that compared  
5 monolingual and bilingual performance in non-verbal inhibition tasks, investigating their  
6 data trimming procedures. If bilingual advantages are at least partly located in the tails of  
7 response distributions, i.e. in the slow responses as in Calabria et al. (2011), then one  
8 would expect that cutting off slow responses would reduce the chance of finding such  
9 advantages. We focused on three non-linguistic inhibition tasks that have been most  
10 intensely used to investigate the bilingual advantage: the Simon task, the Spatial Stroop  
11 task and the Flanker task (the latter sometimes embedded in an ANT). To ensure  
12 comparability, some variations of the tasks were excluded (e.g. the Simon task with a  
13 delay component in Martin-Rhee & Bialystok, 2008). We found 68 experiments taken  
14 from 33 articles (see Table 1). Within these 68 experiments, 23 (34%) reported data  
15 trimming procedures, 4 reported excluding very short responses but did not report  
16 trimming of response distribution tails, 1 stated explicitly that long responses were not  
17 trimmed and the remaining 40 did not mention whether or not they trimmed the data. For  
18 the purpose of our analyses, we treated the latter studies as ones that did not trim the data.

36  
37  
38 [Table 1 About Here]

39  
40  
41 Two issues need to be pointed out. First, for studies that did trim the data, the  
42 practices differed. While some studies rejected long responses using standard deviations  
43 (e.g. 2.5 *SD* in Paap & Greenberg, 2013, which was approximately 700 ms after stimulus  
44 onset), others used a specific time cut-off (e.g. response times above 1700 ms). For  
45 comparison purposes, we translated cut-offs based on standard deviations into time cut-  
46 offs (using reported means and standard deviations). Second, for studies that did not trim  
47 the data, there was a big variation in terms of the maximum time allowed for making a  
48  
49  
50  
51

54  
55  
56  
57  
58  
59  
60

1  
2  
3 response. For example, in Kousaie and Phillips (2012) 750 ms were allowed for making a  
4  
5 response, meaning that in this particular design it was not possible to observe responses  
6  
7 slower than 750 ms. This is equivalent to trimming the data at 750 ms. For these reasons,  
8  
9 we focused on maximum response times being included in analyses (Figure 1). For  
10  
11 studies that did report a data trimming procedure, this is either the explicitly stated cut-off  
12  
13 time or the RT calculated by the mean and *SD*. For studies that did not report a data  
14  
15 trimming procedure, this was the maximum time allowed for making a response. For  
16  
17 simplicity reasons, we will refer to both types of trimming as the maximum response time  
18  
19 allowance.  
20  
21  
22  
23

24  
25 We acknowledge that data trimming and varying maximum time allowances are  
26  
27 not the same. Different maximum time allowances, but not data trimming, can lead to  
28  
29 different response strategies. For example, participants might not monitor their response  
30  
31 accuracy as thoroughly in an experiment with a response allowance of 1000 ms compared  
32  
33 to an experiment with a response allowance of 5000 ms and data trimming at 1000 ms.  
34  
35 However, in none of the 16 studies in the long allowance group data trimming was  
36  
37 applied, which means that this cannot have affected our results.  
38  
39  
40

41  
42 Some of the studies reviewed were not included into further analysis because  
43  
44 there was not adequate information about either the maximum time allowed or how the  
45  
46 data was treated (the 3<sup>rd</sup> study in Bialystok, Martin, et al., 2005, all studies in Gathercole  
47  
48 et al., 2014, Yang et al., 2011, and Mohades et al., 2014). Carlson and Meltzoff (2008)  
49  
50 was not included either because they did not report RTs. This led to 58 studies being  
51  
52 included in our statistical analysis.

Figure 1 shows the number of experiments that did and did not find a bilingual advantage for the various maximum times allowed. A clear pattern emerges: the shorter the maximum response time allowance, the less likely that a bilingualism effect was found. In order to statistically test whether observing a bilingualism effect depends on the maximum time allowed, we grouped the experiments into three types of maximum time allowance: short allowance (below 1000ms), medium allowance (1001ms – 3000ms) and long allowance (above 3001ms; see Table 2). A chi-square test of independence confirmed that the result patterns differed for the three allowance groups,  $\chi^2(2, N = 58) = 21.99, p < .001$ . Thus, consistent with our hypothesis, studies with short response time allowance were more likely to report no group difference whereas studies with longer allowance were more likely to report a bilingualism effect.

[Table 2 About Here]

In a meta-analysis of the bilingual advantage literature, Donnelly, Brooks, & Homer (2015) reported an effect of research lab. They suggested that this effect might be due to lab differences in, for instance, access to bilingual populations. In our long allowance group (>3001 ms), many studies are from the same research group. In fact, 14 out of 16 data points are from a research group around one particular author. In order to rule out that the current result is driven by a potential effect of lab, we excluded all data point from this lab. This led to two data points in the long allowance group. We therefore focussed on the short and medium allowance group, which both constituted a mixed contribution from different labs, meaning that the new result could not have been driven by any lab effect. This analysis confirmed our original result. The likelihood of observing a bilingualism effect depended on RT allowance,  $\chi^2(1, N = 42) = 12.14, p < .001$ , with

1  
2  
3 the medium allowance group being more likely to observe a bilingualism effect than the  
4  
5 short allowance group.  
6  
7

8 As introduced, it has been pointed out that the age of the participants might play a  
9  
10 role in whether a bilingualism effect can be detected or not. More specifically, bilingual  
11  
12 elderly have been found to show the cognitive control advantage more consistently than  
13  
14 other age groups. In addition, elderly and children respond on average much slower than  
15  
16 adults. It might therefore be that our result arose because the group with long response  
17  
18 allowances might have consisted of studies with very young and very old populations.  
19  
20 We therefore tested the relationship between maximum response time allowance and the  
21  
22 likelihood of finding a bilingualism effect in children, adults and elderly participants  
23  
24 separately (see Table 2). A chi-square test of independence showed that while the  
25  
26 relationship was not significant for children,  $\chi^2(2, N = 10) = 2.86, p = .24$ , it was  
27  
28 significant for adults,  $\chi^2(2, N = 37) = 13.40, p = .001$ , and was marginally significant for  
29  
30 elderly participants,  $\chi^2(2, N = 11) = 5.29, p = .071$ . The non-significant result for the  
31  
32 children was likely driven by limited power due to small numbers, especially in the short  
33  
34 allowance category. Nevertheless, descriptively 83% (5 out of 6) of the studies in the  
35  
36 long allowance group versus 66% (2 out of 3) in the medium allowance group showed a  
37  
38 bilingualism effect. This result pattern is consistent with the conclusion that studies with  
39  
40 longer response allowances are more likely to show a bilingualism advantage. Similarly  
41  
42 in the elderly group, studies with longer allowances are more likely to report a  
43  
44 bilingualism effect descriptively. The marginal effect seems again be due to a small  
45  
46 sample size. In summary, it appears that data trimming reduces the likelihood of  
47  
48 observing a bilingualism effect regardless of age group. Also, the very robust finding for  
49  
50  
51

9

## 10 **Discussion**

11  
12 Based on the assumption that the effect of bilingualism on cognitive control  
13 resides at least partly in the tail of response distributions, we investigated a potential  
14 relationship between data trimming procedures adopted and the likelihood of observing a  
15 bilingualism effect by reviewing 68 experiments reported in 33 articles that compared  
16 monolingual and bilingual speakers using non-verbal interference tasks. We found that  
17 studies that included longer responses in their analysis were more likely to report a  
18 bilingualism effect, either in the form of overall response speed advantage or in the form  
19 of reduced interference effect. And this was also the case when the potential effect of lab  
20 was eliminated. This is consistent with earlier findings that the bilingualism effect  
21 emerges partially in the tail of response distributions (Abutalebi et al., 2015; Calabria et  
22 al., 2011; Tse & Altarriba, 2012). It appears that, when these prolonged responses were  
23 trimmed or not recorded, group differences might have also been eliminated.

40  
41 A further analysis showed that the general result pattern was true for studies  
42 testing children, adults and elderly alike, even though significantly so only for adults,  
43 suggesting that data trimming might be problematic independent of the age of the  
44 participants and therefore independent of the average response times or the cognitive  
45 abilities of the participants. It also showed that the overall result pattern was not caused  
46 by studies with participant groups with very long responses times. There is unfortunately  
47 an insufficient number of studies and/or information about the participants in studies

1  
2  
3 published to date to test whether data trimming procedure affects results independent of  
4  
5 other factors that have been suggested to interact with the bilingual advantage (such as  
6  
7  
8 SES, immigrant status, language dominance, age of language acquisition, language usage  
9  
10 etc.) Future studies will need to disentangle the relevance of and the potential interplay of  
11  
12 all these factors.  
13

14  
15 This review provides some practical implications for future endeavours.  
16  
17 Employing a more fine-grid investigation approach might be useful, particularly in  
18  
19 situations where effects are subtle. As pointed out, one fruitful alternative to traditional  
20  
21 approaches of analysis is the ex-Gaussian analysis of response time distributions  
22  
23 (Abutalebi et al., 2015; Calabria et al., 2011). For instance, Abutalebi et al. (2015)  
24  
25 reported that a group of bilingual elderly showed advantage in the  $\tau$  component in the  
26  
27 incongruent condition and the  $\mu$  component in the congruent condition in a Flanker task,  
28  
29 supporting the notion that bilingual speakers have enhanced attentional control. It has to  
30  
31 be pointed out, though, that one needs to be cautious when interpreting the results from  
32  
33 ex-Gaussian parameters in terms of underlying cognitive processes, because there is no  
34  
35 one-to-one mapping between cognitive processes and those parameters (Matzke &  
36  
37 Wagenmakers, 2009).  
38  
39  
40  
41  
42

43  
44 An alternative approach to the ex-Gaussian analysis is a delta plot analysis, which  
45  
46 examines condition effects as a function of RT and which has been used in analysing  
47  
48 conflict tasks such as the Simon task and the Colour Stroop task (Ridderinkhof, 2002a,  
49  
50 2002b; Ridderinkhof, Wildenberg, Wijnen, & Burle, 2004). In delta plot analyses,  
51  
52 responses for each condition are grouped into bins according to their response times.  
53  
54  
55 Condition differences are then calculated and plotted for these bins. Delta plots  
56  
57  
58  
59  
60

1  
2  
3  
4 prototypically have a positive slope due to effect sizes being larger for slower responses  
5  
6 (Roelofs, Piai, & Garrido Rodriguez, 2011). If one condition requires more inhibition  
7  
8 than the other, the difference between conditions does not linearly increase with RT, but  
9  
10 is reduced instead, resulting in ‘levelling-off’ of the delta plot in longer RTs. The  
11  
12 levelling-off has been explained by inhibition building up slowly (Ridderinkhof, 2002a).  
13  
14 The extent to which the plots level off can effectively reflect the amount of inhibition  
15  
16 involved. The stronger the inhibition is applied, the smaller the slope of the plot is. For  
17  
18 example, Ridderinkhof (2002b) observed that in a Simon task, delta plots for participants  
19  
20 with smaller Simon effect, who are believed to have more efficient inhibitory control,  
21  
22 levelled off more than those with larger Simon effect. Because a delta plot analysis is  
23  
24 most useful within the discussion of inhibitory control, this approach could be used to test  
25  
26 whether inhibition was applied equally fast and to the same degree in monolinguals and  
27  
28 bilinguals.  
29  
30  
31  
32  
33

34 In conclusion, the current review adds to the discussion about the reality of the  
35  
36 bilingualism cognitive advantage in that seemingly insignificant details such as data  
37  
38 trimming and maximum time allowed for response might have a significant influence on  
39  
40 the findings. Therefore, it is important to take these into account in order to fully judge  
41  
42 the evidence for and against a bilingual cognitive effect, next to other factor already  
43  
44 pointed out in the literature. In addition, future studies are encouraged to report in detail  
45  
46 how data were handled and possibly use more fine-grid analyses of RT data to shed light  
47  
48 onto the effect of bilingualism on speakers’ cognitive control abilities.

1  
2  
3  
4  
5 Note: 1. Overall = Bilingual advantage in overall response speed (in both congruent and incongruent condition). Effect = Smaller  
6 congruency effect for bilinguals. 2. Study 4 and 5 in this article were the same as in Bialystok (2004); therefore we do not  
7 duplicate report here. 3. Bilingual overall advantage was found in the Cantonese/English bilingual group but not the  
8 French/English bilingual group; this is represented as two separate comparisons here. 4. Not stated directly, but followed the  
9 procedure by Bialystok et al. (2004). 5. Another two variations of the Simon task were conducted, with a short or a long delay.  
10 These were not included here. 6. A bilingual advantage was reported for response accuracies. Information regarding response  
11 speed is not available. 7. Assuming that responses can be made during the blank interval of 300 ms after the stimulus presentation  
12 for 1000 ms. 8. Yudes et al. (2011) also tested a group of simultaneous interpreters. We only report the monolingual/bilingual  
13 comparison. 9. A group of second language learners and a group of trilingual children were also tested. We only report the  
14 monolingual/bilingual comparison. 10. Not stated directly, but followed the procedure by Costa et al. (2008). 11. Kirk (2013)  
15 tested three monolingual control groups. We only report results regarding Anglo-English monolingual group which does not  
16 speak another dialect. Kirk (2013) also reported analysis without removing outlying responses and found no group difference. 12.  
17 Blumenfeld & Viorica (2014) also reported reverse efficiency scores which were based on both response latencies and accuracy  
18 rates. This analysis yielded slightly different result patterns. We focus on response latencies for reasons of comparability.

*Number of Experiments with Short, Medium or Long Cut-offs / Maximum Allowed Times and Findings of Bilingual Advantage*

| Cut-off Group    | Children   |           | Adults     |           | Elderly    |           | Overall    |           |
|------------------|------------|-----------|------------|-----------|------------|-----------|------------|-----------|
|                  | No         | Bilingual | No         | Bilingual | No         | Bilingual | No         | Bilingual |
|                  | Difference | advantage | Difference | advantage | Difference | advantage | Difference | advantage |
| Short Allowance  | 1          | 0         | 16         | 2         | 3          | 1         | 20         | 3         |
| Medium Allowance | 1          | 2         | 5          | 8         | 2          | 1         | 8          | 11        |
| Long Allowance   | 1          | 5         | 1          | 5         | 0          | 4         | 2          | 14        |
| Column Total     | 3          | 7         | 22         | 15        | 5          | 5         | 30         | 28        |
