Abstract

We report concentrations of brominated flame retardants (BFRs) in 23 plastic samples from 20
new and second-hand children's toys sourced from the UK that had been previously shown to be
Br-positive by XRF. The results reinforce existing evidence that the recycling of BFR-treated
electronic plastics has led to the unintentional BFR contamination of articles not required to be
flame-retarded. The principal BFRs detected were PBDEs (and in particular BDE-209), HBCDD
and TBBP-A. PBDEs were detected in all samples with a maximum concentration of BDE-209
of 2500 mg/kg, and while TBBP-A was detected in 11 samples with a maximum concentration
of 3100 mg/kg. HBCDD was detected in 14 cases and was present in four toys at concentrations
(139-840 mg/kg) that would currently prevent their sale on the EU market. While estimated
exposures to PBDEs via accidental ingestion of toy plastic fell well below USEPA reference
doses, a child weighing 8.67 kg and ingesting 8 mg/day of a toy (the default assumption of the
European Commission's Toy Safety Directive for scraped-off toy material) contaminated at our
arithmetic mean concentration would be exposed to 0.2 ng/kg bw/day BDE-99. This compares
closely to a health-based limit value (HBLV) proposed in The Netherlands of 0.23-0.30 ng/kg
bw/day BDE-99. Of greater concern, the same child playing with a toy contaminated at the
maximum concentration in this study would be exposed to 1.4 ng/kg bw/day BDE-99, thereby
exceeding the HBLV. This paper is the first to consider BFR exposure via incidental ingestion of
plastic from both contemporary and historical toys, revealing it to be considerable and for some
children their most significant pathway of exposure.

39

36

40 Highlights

- 41 Br and BFRs measured in children's plastic toys
- 42 HBCDD present in 4 toys at concentrations above the EU UTC limit value
- PBDE concentrations in 2 toys exceed proposed limit of 500 mg/kg
- TBBP-A detected in 11 samples
- 45 Children's exposure via unintentional ingestion of toy plastic may be substantial

1. INTRODUCTION

Due to evidence of their adverse health effects, brominated flame retardants (BFRs) such as polybrominated diphenyl ethers (PBDEs) and hexabromocyclododecane (HBCDD) are subject to global bans and restrictions. As a consequence, reports of the presence of BFRs in plastic children's toys as a result of the use of recycled polymers containing such chemicals are of concern (Chen et al., 2009; Ionas et al., 2014; DiGangi et al., 2017; Guzzonato et al., 2017; Puype et al., 2019; Straková and Petrlík, 2017). Children are particularly vulnerable to the adverse health effects of contaminants because of their behavioural tendencies (*e.g.*, mouthing of objects and hand to mouth activities) that differ from adults and result in higher levels of exposure (Landrigan et al., 2011).

To protect children from migratable substances in toys, the Toy Safety Directive (TSD) 2009/48/EC was introduced by the EU (European Commission, 2009). It stipulates that substances classified as carcinogenic, mutagenic, or toxic for reproduction (category 1A, 1B, or 2 and referred to as CMRs) shall not be used in toys or components thereof. While Br and BFRs are not specified under the TSD, in an effort to prevent the contamination of new plastic articles with PBDEs and HBCDD, the EU introduced low persistent organic pollutant (POP) concentration limits (LPCLs). Waste articles, such as plastic casings of end-of-life electronic equipment, that contain HBCDD or PBDEs present in the Penta- and Octa- (and, since 2019, Deca-) BDE formulations at concentrations exceeding the LPCL of 1,000 mg/kg cannot be recycled until their PBDE and HBCDD content has been destroyed or irreversibly transformed (European Commission, 2014; 2016). However, the LCPL is currently being reviewed with the aim of adopting legislative limits that are lower than 500 mg/kg as quickly as possible and no later than 2021 (European Commission, 2019). Moreover, the EU has also introduced an Unintentional Trace Contaminant (UTC) limit for HBCDD of 100 mg/kg (European

Commission, 2016), with UTC limits for tetra-, penta-, hexa-, hepta- and decaBDE of 10 mg/kg 72 73 each to be introduced in July 2021 (European Commission, 2019). 74 75 In addition to PBDEs and HBCDD, other BFRs have been used in a variety of applications to 76 impart flame retardancy to polymers such as electrical items and fabrics. The most widely used 77 of these is tetrabromobisphenol-A (TBBP-A) (Abdallah, 2016), while others such as 78 decabromodiphenyl ethane (DBPDE), pentabromobenzene (PBBz), hexabromobenzene (HBB), 79 pentabromotoluene (PBT), and pentabromoethylbenzene (PBEB) are also reported to have been 80 used (Covaci et al., 2011). As use of the latter five BFRs is thought to have increased in recent 81 years in response to restrictions on "legacy" BFRs like PBDEs and HBCDD, compounds such as 82 DBDPE, PBBz, HBB, PBT, and PBEB are collectively referred to here as "novel" BFRs (or 83 NBFRs). While TBBP-A and these NBFRs are not subject to restriction, their presence in, for 84 example, indoor air has been demonstrated (Abdallah et al., 2008; Cequier et al., 2014; Newton 85 et al., 2015), and concerns have emerged over their potential adverse health effects (Covaci et al., 86 2009; Nakari and Huhtala, 2009; Ezechiáš et al., 2012). Given the widespread use of such BFRs, 87 similar concerns exist that they may be present in items containing recycled plastics, with 88 DBDPE being reported to be present in children's plastic toys purchased in China (Chen et al., 89 2009). 90 91 Previously, 200 second-hand plastic toys (encompassing plastic components from multi-material 92 toys) sourced in the UK were analysed by X-ray fluorescence (XRF) spectrometry for the 93 presence of hazardous elements (As, Ba, Cd, Cr, Hg, Pb, Sb, Se) regulated in children toys under

Fatunsin et al, 2019 Page 5 of 28

the TSD, with Br as a proxy metric of BFRs also analysed and detected in many cases (Turner,

2018a). A subsequent study also found Br in many plastic toys that had been purchased new,

with the majority of Br-positive items black in colour and consistent with the recycling of

94

95

electronic waste plastic that is often black for cosmetic and economic purposes (Turner, 2018b). The overall aim of this study, therefore, was to measure concentrations of various legacy (*i.e.* PBDEs and HBCDD) and NBFRs in a selection of toys sourced in the UK that had been shown to be Br-positive (Turner, 2018b), and to use these data to conduct an assessment of exposure of children playing with such toys and the associated health risk. As previous studies of this topic had not considered exposure via inadvertent ingestion of plastic particles, we further aimed to examine such exposure to test the hypothesis that this pathway is a significant source of exposure to infants. Subsidiary aims were to: (a) evaluate the extent to which measurements of elemental Br in toys are attributable to our target BFRs, and (b) identify any exceedances of the EU's current and impending LPCL and UTC limit values for PBDEs and HBCDD.

2. MATERIALS AND METHODS

2.1. Sampling and screening for total Br via XRF

Twenty three plastic components (samples) from 20 new and second-hand toys (Table 1) previously shown to contain Br that is believed to be derived in whole or in part from the recycling of electronic waste plastic (Turner, 2018a; 2018b) were selected for this study. Sample #s 4, 10, and 23 originated from new toys, with all other samples taken from second-hand items. Toys included game pieces, vehicles, parts of figures, items of jewellery and the handle of a dummy. As an additional check on the total Br content of each sample, and to assess the homogeneity of the distribution of Br, a NITON XL3t 700XRF spectrometer was used to make measurements at between two and four points on each sample (Table 1). Before analysis, the surface of each sample was wiped with a clean non-fibrillating tissue to remove any surface dust. The instrument window was then placed as flat as possible against the sample surface and a measurement of Br content conducted for 60 seconds. The limit of quantification for Br was 5 mg/kg. Calibration of the XRF was performed by Niton UK using proprietary standards

122	containing varying concentrations of relevant inorganic compounds in a polymer matrix. The
123	instrument was operated in a low density "plastics" mode and with thickness correction.
124	
125	2.2. BFR measurement methods
126	2.2.1. Chemicals and reagents
127	HPLC-grade solvents were used for sample extraction and LC-MS/MS analysis (Fisher
128	Scientific, Loughborough, UK). Concentrated sulphuric acid was purchased from Sigma-Aldrich
129	(St. Louis, MA, USA). Individual α -, β - and γ -HBCDD standards, $^{13}C_{12}$ α -, β - and γ -HBCDD,
130	d ₁₈ -γ-HBCDD, individual standards of PBDEs 17, 28, 47, 49, 77, 99, 100, 153, 154, 183,196,
131	$197, 209 \text{ and } 128, {}^{13}\mathrm{C}_{12}\text{-BDE-}209, TBBP-A, {}^{13}\mathrm{C}_{12}\text{-TBBP-A}, PBBz, PBT, PBEB, HBB, and {}^{13}\mathrm{C}_{6}\text{-}$
132	HBB and DBDPE were purchased from Wellington Laboratories (Guelph, ON, Canada).
133	Polychlorinated biphenyl (PCB)-129 was obtained from Qmx laboratories (Thaxted, UK). A
134	certified reference material (CRM) for polypropylene (ERM-EC591), containing certified
135	concentrations of PBDEs, was purchased from IRMM (Brussels, Belgium).
136	
137	2.2.2. BFR extraction and extract purification
138	Samples were analysed for concentrations of BFRs using a validated in-house method (Abdallah
139	et al., 2017). Briefly, accurately weighed 0.2 g aliquots of each sample where Br was detected by
140	XRF were transferred into 15 mL glass centrifuge tubes and spiked with 20 ng of internal
141	standards ($^{13}C_{12}\alpha$ -, β - and γ -HBCDD, $^{13}C_{12}$ -BDE 77, $^{13}C_{12}$ -BDE-128, $^{13}C_{12}$ -TBBP-A and $^{13}C_{6}$ -
142	HBB) as well as 40 ng 13 C ₁₂ -BDE 209. Samples were extracted with 3 mL CH ₂ Cl ₂ by vortexing
143	for 2 min and sonicating for 5 min. This was repeated with two further 3 mL aliquots of fresh
144	CH ₂ Cl ₂ . Extracts were collected and combined in a separate centrifuge tube and evaporated to
145	near dryness at 40 °C under a gentle stream of nitrogen before being reconstituted in 2 mL of
146	hexane and vortexed to precipitate dissolved plastics. The hexane supernatant was collected and

147	washed with 2 mL of >98 % concentrated sulphuric acid before vortexing for 30 s. Samples
148	were left for 2 h followed by centrifugation at 3000 rpm for 5 min to ensure complete separation
149	of the organic layer. The clean supernatant hexane layer was collected in a glass tube and
150	concentrated to near dryness before reconstitution in 200 μL of toluene containing 0.1 ng/ μL
151	PCB-129 and d ₁₈ -γ-HBCDD for recovery determination (or syringe) standards. The extracts were
152	transferred to auto-sampler vials with glass inserts for quantitative analysis of PBDEs, PBBz,
153	and DBDPE on GC/MS. After GC-MS analysis, the same extracts were solvent-exchanged to
154	methanol ready for determination of HBCDDs and TBBP-A via LC-MS/MS.
155	
156	2.2.3. Instrumental Analysis
157	Determination of PBDEs and NBFRs was conducted on a ThermoFisher Trace 1310 gas
158	chromatograph coupled to a ThermoFisher ISQ mass spectrometer operated in electron
159	ionization mode and using selective ion monitoring. With a programmable temperature
160	vaporizer, 1 μL of extracts were injected onto a Restek Rxi-5Sil MS column (15 m \times 0.25 mm \times
161	$0.25~\mu m$ film thickness) with He as the carrier gas at a flow rate of 1.5 mL/min (Abdallah et al.,
162	2017).
163	
164	HBCDDs and TBBP-A were quantified on a Shimadzu LC-20AB prominence binary pump
165	liquid chromatograph equipped with a SIL-20A auto-sampler, and a DGU-20A3 vacuum
166	degasser coupled to an AB Sciex API 2000 triple quadrupole MS (Abdallah et al., 2017). An
167	Agilent Pursuit XRS3 C18 column (150 mm \times 2 mm id, 3 μ m particle size) eluted with a mobile
168	phase of (i) 1:1 methanol/water with 2 mM ammonium acetate and (ii) methanol at a flow rate of
169	$180\;\mu\text{L/min}.$ The mass spectrometer was operated in negative ESI mode. MS/MS detection
170	operated in the multiple reaction monitoring mode was used for quantitative determination of
171	HBCDD isomers based on m/z 640.6 \rightarrow 79, m/z 652.4 \rightarrow 79, and m/z 657.7 \rightarrow 79 for the native,

 13 C-labelled and d₁₈-labelled HBCD diastereomers, respectively and m/z 540.8 → 79, m/z172 $552.8 \rightarrow 79$ for the native and ¹³C-labelled TBBP-A, respectively. 173 174 175 2.2.4. QA/QC Average recoveries of internal standards were between 65 % and 78 %. Table SI-1 shows that 176 177 the concentrations of PBDEs detected in an aliquot of the certified reference material ERM-178 EC591 compared favourably with the certified values. Limits of quantification (LOQs) were 179 estimated from a signal to noise ratio of 10:1; target compounds were not detected above LOOs 180 in the blanks and results were therefore not corrected for blank residues. Table SI-2 gives the 181 LOQs for all target compounds. 182 183 2.3. Data analysis 184 For the purposes of calculating descriptive statistics, <LOQ values were replaced by fx LOQ, where f = the detection frequency of a given BFR expressed as a decimal fraction. 185 186 187 2.4. Exposure estimation methods 188 2.4.1. Exposure via oral ingestion Exposure via oral ingestion (E_{oral ingestion} in ng/kg body weight/day) was estimated using the 189 190 following algorithm: 191 $E_{\text{oral ingestion}} = C_{\text{toyx}} m_{\text{x}} (BA/BW)$ where C_{toy} is the BFR concentration in the toy (in ng/g), m is the mass of toy ingested per day 192 which, by default, is 8 mg/day according to the Toy Safety Directive (Lenzner et al., 2018), BA is 193 194 the bioavailability of the BFR (%), assumed conservatively to equal the bioaccessibility of BFRs 195 of dust in simulated gastrointestinal tract fluid (Abdallah et al., 2012), and BW is body weight 196 (kg).

1	9	7

2.4.2. Exposure via dermal uptake

We estimated exposure via dermal uptake (E_{dermal} in ng/kg body weight/day) as follows:

$$E_{\text{dermal}} = C_{\text{tov}}^* \times PSA \times IEF \times (AF/BW)$$

Here, C_{toy}^* is the BFR concentration of BFR in toy the (in ng/m²) ($C_{\text{toy}}^* = 1.4 \times 0.05 \times C_{\text{toy}}$ assuming a 0.05 cm depth of surface and a density of 1.4 g/cm³ equivlent to acrylonitrile butadiene styrene) (Kuang et al., 2018), PSA is the palm surface area exposed dermally to the toy (assumed to be 0.0986 m²) (Chen et al., 2009), IEF is the indoor exposure fraction, or the number of hours per day for which dermal contact with toys occurs (assumed to be 2; Chen et al., 2009), and AF is the absorbed fraction. The latter is based on measured data for the dermal uptake of PBDEs and HBCDD from fabrics over a 24 h contact (Abdallah and Harrad, 2018) and measured data for 24 h contact with solutions of TBBP-A (Abdallah et al., 2015), and is normalised for a 2 h period.

3. RESULTS AND DISCUSSION

3.1. Concentrations of Br and BFRs in children's plastic toys

Table 2 reports the average of the replicate measurements of total Br made by XRF for each toy,

including components thereof, while Table SI-3 lists each individual Br measurement for these

samples. In some cases, total Br appears to be uniformly distributed in the plastic, while in other

cases there is evidence for its heterogeneous dispersion in the toy. Table 2 also lists

concentrations of the target BFRs in each sample, as well as the median, arithmetic mean, and

maximum concentrations for the whole dataset.

BFRs were detected in all toys tested with summed concentrations ranging from 1.4 mg/kg to about 6140 mg/kg. The principal BFRs detected in the toys were either PBDEs (in particular

BDE-209), HBCDD or TBBP-A, with only low concentrations detected of our target NBFRs.

223 The newest toys, purchased in 2017, contained < 20 mg/kg of BFRs but displayed a wide range 224 in compounds historical and new BFRs. Overall, the BFR pattern and absolute concentrations in 225 our samples are within the range of those previously reported for other studies of plastic items 226 containing recycled polymers, including toys and food contact articles (Chen et al., 2009; 227 Guzzonato et al., 2017; Ionas et al., 2014; Kuang et al., 2018; Puype et al., 2015, 2017). 228 229 If our study has quantified all of the Br-containing compounds in a sample, then the total Br and 230 ΣBFR concentrations should be broadly equal, with the latter slightly exceeding the former 231 because Br only constitutes a proportion of the mass of any BFR. Moreover, as we measured 232 BFRs in a single small aliquot of each toy or component thereof and our replicate XRF 233 measurements of Br revealed varying degrees of inhomogeneity of Br distribution within the 234 sample, Br and ΣBFR measurements will deviate in some instances. Specifically, the 235 heterogeneous distribution of Br and BFRs likely explains why ΣBFRs > average Br in sample #s 5 ($\Sigma BFRs = 847 \text{ mg/kg c.f. Br} = 90 \text{ mg/kg}$) and 6 ($\Sigma BFRs = 468 \text{ mg/kg c.f. Br} = 289 \text{ mg/kg}$); 236 237 thus, in sample #5, while Br was <LOQ at 2 measurement points, it was 269 mg/kg at a third, 238 and in sample #6, while Br was <LOQ at 1 measurement point, it was 578 mg/kg in the other. 239 Conversely, where Br exceeds \(\Sigma BFR \) substantially for a given sample (e.g., sub-samples #15, 16 240 and 17 from the same toy) this implies that there is another source or sources of Br in that 241 sample. This may either be an organobromine compound, like the NBFR, BTBPE, which was 242 not measured here but was detected at 1,100 mg/kg in a UK plastic kitchen utensil (Kuang et al., 243 2018), a polymeric BFR (Gouteux et al, 2008; Puype et al, 2017) or an inorganic Br compound. 244 Despite these discrepancies, however, there was a significant relationship between Br and ΣBFR among the samples, with linear regression analysis returning a best fit line of Br = $1.39 \Sigma BFR +$ 245 $208 (r^2 = 0.840, p < 0.05).$ 246

248	3.2. Do concentrations of PBDEs and HBCDD in toys exceed LPCL and/or UTC limit values?
249	Two of the samples analysed (#s 2 and 8) exceed the proposed LPCL value of 500 mg/kg for the
250	summed concentrations of PBDEs (including Deca-BDE), and three additional samples (#s 6, 18
251	and 20) exceed the UTC limit set for July 2021 of 10 mg/kg for Deca-BDE alone. With regard to
252	HBCDD, four samples (#s 2, 5, 11 and 12) exceed the UTC limit of 100 mg/kg, although all
253	were purchased before the limit was introduced (March 2016). Overall, eight out of the 23 sub-
254	samples analysed exceed current or impending limit values for restricted BFRs. In all cases, the
255	items exceeding limits were second-hand and manufactured before 2016. This may suggest that
256	measures to eliminate BFRs from toys containing recycled plastic have been effective; however,
257	we only studied three toys manufactured after these measures were introduced and a much larger
258	study is required to fully evaluate the efficacy of these measures.
259	
260	A recent report revealed the presence of HBCDD in various toys and Rubik's cubes purchased in
261	the Czech Republic, up to a maximum of 91 mg/kg in a toy shoe (Straková et al., 2017). Of even
262	greater concern, an earlier survey of 95 Rubik's cubes and 16 additional child-related items
263	sourced from 26 countries around the world (DiGangi et al., 2017) revealed a maximum HBCDD
264	concentration of 1,586 mg/kg, with two items exceeding the LPCL value at the time of 1,000
265	mg/kg and seven exceeding the UTC limit value of 100 mg/kg.
266	
267	3.3. The presence of TBBP-A and NBFRs in toys
268	Relatively few reports exist of the presence of BFRs other than PBDEs and HBCDD in plastic
269	toys, and we believe this study to be only the second report of TBBP-A in such products. Our
270	data for concentrations of TBBP-A (range not detected to 3,140 mg/kg) suggest a broadly similar
271	level of contamination to that observed in toys from the Czech Republic, Germany, and Italy
272	(range 210 mg/kg - 7,800 mg/kg) (Guzzonato et al., 2017). Only trace quantities of the target

273 NBFRs were detected in our samples, providing reassurance that their presence in plastic toys is 274 not currently of significant concern. 275 276 3.4. What are the human exposure implications of the presence of BFRs in toys? 277 The potential for human exposure arising from the presence of PBDEs in toys has previously 278 been evaluated (Chen et al., 2009; Ionas et al., 2014). These studies identified potential for 279 exposure via inhalation arising from volatilization of PBDEs, mouthing, dermal contact and oral 280 ingestion (transfer of PBDEs to hands and subsequent oral exposure). As both studies employed 281 the same exposure assessment algorithms, the relative importance of the four exposure pathways 282 was identical in both instances. In summary, exposure via mouthing was estimated to 283 predominate for pre-school children, with exposures via the other pathways making relatively 284 minor contributions. While the absolute estimated exposure levels varied due to the differences 285 in BFR concentrations in toys between the two studies, neither study identified exposures via 286 contact with toys to be of significant toxicological concern. 287 288 Detailed examination of the input data employed to estimate exposure via inhalation, dermal 289 contact, and oral ingestion (Chen et al., 2009; Ionas et al., 2014) reveals the key input parameter 290 in each case to be an emission factor derived for volatilization of PBDEs from flame-retarded 291 items like television sets (Kemmlein et al., 2003). While constituting a useful approach to 292 scoping exposure via these pathways, volatilization emission factors from source items 293 containing PBDEs at concentrations well in excess of those present in plastic toys are predicted 294 to overestimate inhalation exposures and are less appropriate when extrapolated to the estimation 295 of dermal and oral ingestion pathways. Similar considerations apply to the volatilization

emission factors reported previously (Kemmlein et al., 2003) for HBCDD (for which the

emission factors are from flame-retarded expanded and extruded polystyrene), while published

296

emission factors for TBBP-A and DBDPE do not appear to be available (Kemmlein et al., 2003)
Regarding mouthing exposure, Chen et al. (2009) based their estimates on experimentally-
derived measurements of BFR migration from two toy samples into human saliva. However, the
data obtained are expressed as pg/cm ² /minute rather than as a proportion of the BFR mass
present in these toys and cannot thus be extrapolated to estimate migration from toys containing
different BFR concentrations such as ours. More recently, exposure to a variety of organic
contaminants (but not BFRs) present in plastic children's toys has been evaluated, based on
inadvertent oral ingestion of small quantities of plastic and subsequent uptake via the
gastrointestinal tract (Lenzner et al., 2018).
Given the aforementioned considerations, we evaluate for the first time exposure to BFRs
measured in plastic children's toys for: (a) the oral ingestion of 8 mg/day of toy plastic (in line
with the default assumption of the Toy Safety Directive for scrapable toy material), and (b)
dermal uptake arising from a child handling toys. As Chen et al. (2009) identified infants aged
between 3 and 18 months (and of body weight 8.67 kg) to be at greatest risk, we have evaluated
exposure for this age group only.
Table 3 summarizes our estimates of typical and high-end exposure via both pathways identified
above ($E_{\text{oral ingestion}}$ and E_{dermal}) and obtained using both the arithmetic mean and the maximum
BFR concentrations, respectively, for the samples shown in Table 2. It is very clear that while
dermal exposure does occur for young children, exposure arising from accidental ingestion of
plastic from toys is orders of magnitude greater. Also shown in Table 2 are previously published
typical and high-end exposure estimates to BFRs for UK children arising from other pathways;
namely: diet (Tao et al, 2017), inhalation (Tao et al, 2016), dust ingestion (Tao et al, 2016),
dermal contact with BFR-containing fabrics and indoor dust (Abdallah and Harrad, 2018), and

323	breast milk consumption (1ao et al, 2017). Typical and high-end estimates arising from each
324	pathway for $\Sigma PBDEs$ and $\Sigma HBCDDs$ are also compared in Figures 1 and 2, respectively.
325	
326	It is evident that exposure via incidental oral ingestion of toy plastic can make a very substantial
327	contribution to overall exposure of young children to our target BFRs. Specifically, under the
328	typical scenarios (where the plastic ingested is assumed to contain BFRs at the arithmetic mean
329	concentration determined in this study, along with typical estimates for other pathways),
330	ingestion contributes 31.8 % of overall exposure to $\Sigma PBDEs$ and 58 % of overall exposure to
331	ΣHBCDD. Under the high-end exposure scenarios (where the plastic ingested is assumed to
332	contain the maximum BFR concentration determined, along with high-end estimates for other
333	pathways), the contribution made by ingestion of toy plastic to overall exposure falls to 17.7 %
334	and 41 % of ΣPBDEs and ΣHBCDD, respectively.
335	
336	We also compared exposures to PBDEs via oral ingestion of and dermal uptake from plastic toys
337	with the reference doses (RfDs) promulgated by the USEPA for BDEs 47 and 99 (= 100 ng/kg
338	bw/day) and BDE 209 (= 7,000 ng/kg bw/day) (US EPA, 2019a; 2019b; 2019c). Reassuringly,
339	even under the maximum exposure scenario estimated exposures arising from toys alone or the
340	combined pathways are well below the respective RfD values. However, our maximum exposure
341	estimate arising from toys alone for BDE-99 (1.4 ng/kg bw/d) exceeds the health-based limit
342	value (HBLV) proposed in the Netherlands (Bakker et al., 2008) of 0.23-0.30 ng/kg bw/day.
343	Moreover, the typical exposure estimate from toys (0.2 ng/kg bw/day) is very close to this
344	HBLV.
345	

4. Conclusions

347	This study provides the first evidence of the presence of a range of BFRs in both new and
348	second-hand toys sourced from the UK. These data add to previous evidence from elsewhere in
349	the world that suggest that recycling of BFR-treated plastics has led to the unintentional but
350	widespread contamination of articles not required to meet flame retardancy regulations. Eight out
351	of the twenty plastic toys examined contained concentrations of PBDEs or HBCDD that would
352	now or in the near future prevent their sale on the EU market. Exposure of young children to
353	BFRs via incidental ingestion of plastic from toys has also been evaluated for the first time.
354	Exposure via this route appears to be considerable and for some individuals and BFRs may
355	represent the most significant pathway via which they are exposed.
356	
357	SUPPORTING INFORMATION
358	Tables showing: (1) concentrations of PBDEs detected in a certified reference material compared
359	to certified values, (2) limits of quantification for target BFRs, and (3) concentrations of total Br
360	detected in replicate measurements made for each toy.
361

<LOQ denotes not detected

^a for purposes of calculating descriptive statistics, where concentration <LOQ the value has been replaced with f_X LOQ where f = detection frequency of BFR expressed as a decimal fraction

^b Low POP Concentration Limit for ΣPBDEs – to be enforced from 2021 ^c Unintentional Trace Contaminant limit value for BDE-209 – to be enforced from 2021 ^d Unintentional Trace Contaminant limit value for HBCDD – current since 2016

Table 3: Estimated exposures (ng/kg bw/day) to BFRs of young children associated with plastic toys and other pathways

Exposure pathway/scenario	BDE- 47	BDE- 99	BDE- 209	ΣPBDEs	ΣHBCDD	ΣNBFRs
E _{oral ingestion} (typical) ^a	0.2	0.2	21	35	64	0.0001
$E_{ m oral ingestion}$	1.3	1.4	318	520	634	160
(high-end) ^a						
$E_{\text{dermal}} (\text{typical})^{\text{b}}$	0.001	0.001	-i	0.01	0.2	i -
E_{dermal} (high-end) ^b	0.007	0.006	i -	0.092	2.0	_i
Diet (typical) ^c	nr	nr	nr	4.8	1.0	3.0
Diet (high-end) ^c	nr	nr	nr	26	6.2	19
Breast milk (typical) ^d	17	5.9	0.65	35	17	18
Breast milk (high-end) ^d	41	10	2.8	80	34	350
Dermal contact with dust and	nr	nr	_j	3.9	24	_j
fabrics ^e						
Indoor air inhalation and dust	0.10	0.17	31	33	2.9	32
ingestion (typical) ^f						
Indoor air inhalation and dust	18	28	2200	2300	870	290
ingestion (high-end) ^f						
RfD^g	100	100	7000	-	-	-
$HBLV^h$	-	0.23-	-	-	-	-
		0.30				

^a assuming that child ingests 8 mg day⁻¹ of toy plastic contaminated at arithmetic mean and maximum concentration for "typical" and high-end exposure

b assuming that dermal contact occurs with toys contaminated at the arithmetic mean and maximum concentration for "typical" and high-end exposure

^c "typical" and high-end dietary exposures for UK toddlers (Tao et al., 2017)

d "typical" and high-end exposures for breast-fed UK infants (Tao et al., 2017)

e sum of exposures via dermal contact with indoor dust and BFR-containing fabrics (Abdallah and Harrad, 2018). Note ΣPBDE exposure for this estimate covers only those congeners present in the Penta-BDE formulation detected in a fabric covering from a US sofa

f sum of estimates of exposure of UK toddlers via indoor air inhalation and dust ingestion (Tao et al., 2016). For dust ingestion, "typical" exposure assumes median BFR concentration and mean dust ingestion, high-end exposure assumes 95th percentile BFR concentration and high dust ingestion.

g USEPA Reference dose (US EPA, 2019a; 2019b; 2019c)

^h Health based limit value proposed by Bakker et al. (2008)

i dermal absorption not detected for BDE-209 and not studied for our target NBFRs nr = not reported

Figure 1: Relative contribution (expressed as %of total exposure) of selected pathways to exposure of UK young children to ΣPBDEs under (a) typical and (b) high-end scenarios (note no high-end estimate available of dermal exposure via dust and fabrics)

Figure 2: Relative contribution (expressed as %of total exposure) of selected pathways to exposure of UK young children to ΣHBCDD under (a) typical and (b) high-end scenarios (note no high-end estimate available of dermal exposure via dust and fabrics)
